Economics Working Paper 26104

HOOVER INSTITUTION
434 GALVEZ MALL
STANFORD UNIVERSITY
STANFORD, CA 94305-6010
October 15, 2026

We survey nearly 9,000 CFOs, CEOs and senior executives at firms in the US, UK, Germany, Australia, Canada, Mexico and South Africa in Summer 2026 on AI adoption and its effects on jobs and productivity. We establish four key facts. First, 78% of firms use AI, with US firms expecting to spend $2,000 per employee on AI-related expenditures in 2026, implying around $300 billion in aggregate annual firm spending. This AI spending is highly concentrated, with just 2% of firms accounting for over 50% of total spending. Second, 80% of executives report regularly using AI, with an average use of 2.1 hours per week, up from 1.5 hours per week in Winter 2026, highlighting the rapid growth in managerial AI use. Third, executives report that AI has had essentially no net effect on firm employment over the *last 3 years*, and predict little net impact over the *next 3 years*. These small net effects, however, mask considerable job churn: more than 40% of firms anticipate positive or negative employment effects that roughly offset only in the aggregate. Fourth, executives report AI adoption has raised annual labor productivity growth by 0.2% over the *last 3 years*, a modest impact, but expect a substantially larger 0.6% per annum boost over the *next 3 years*.

1. Introduction

There has been a recent surge in interest around the potential economic effects of AI, with a 20-fold surge in media focus since 2020 alone.[1] A variety of sources, including surveys, Census data, and job postings, yield data on AI adoption rates (e.g., Acemoglu et al. 2022a, 2022b, Baslandze et al. 2026, Bonney et al. 2024, McKinsey 2025). Estimates can differ by more than a factor of ten across studies, possibly because they differ in terms of samples, representativeness, and the nature of the responses.[2] Few sources capture the views of senior business executives, who make the strategic decisions on AI adoption and have the best line of sight on how AI will affect their own firms in the next few years. But senior business executives are particularly likely to have informed views about what is happening in their own firms.

So to collect timely data on the impact of AI, we run surveys every 6 months on senior business executives (CEOs, CFOs, and senior finance managers) about AI usage and its effects *at their own firms* over the past three years and, *looking ahead*, what they anticipate over the next three years. We then aggregate their responses. We first fielded parallel survey questions to representative samples of senior executives in the US, UK, Germany, and Australia between November 2025 and January 2026. We ran a second wave between May and July 2026, adding data from Canada, Mexico, and South Africa in addition to the original four countries.

Our surveys yield four key results.

First, AI technologies are already in wide use and spreading rapidly. On average, across the seven countries surveyed in mid-2026, 78% of businesses currently use some AI technology. At the beginning of 2026, 69% did. The most commonly cited uses are 'Generative AI' followed by 'visual content creation' and 'data processing using machine learning'. We also find substantial heterogeneity in the use of AI technologies. Larger, more productive, and higher-paying firms are more likely to deploy AI technologies. Older firms and those with older directors have lower usage rates. Looking ahead, 82% of executives expect their firms to use some form of AI in the next three years.

---

[1] See, for example, the AI media coverage index available here: https://www.policyuncertainty.com/aieu_daily.html

[2] For example, McKinsey (2025) estimate around 88% of businesses use AI in a paid internet survey. Bonney et al. (2024) estimate that around 9% used AI based on the US Census Business Trends and Outlook Survey (BTOS). The ten-fold difference between these sources illustrates challenges with survey data on AI adoption by businesses. It is not clear whether the McKinsey survey's respondents come from a representative sample of businesses. BTOS does have a representative sample of US firms, but the respondents might not be executives who are informed about the firm's strategic adoption of AI and its potential effects on the business

Many businesses are spending sizable amounts on AI adoption. In the US about 30% of businesses plan to spend more than $1,000 per employee on AI in 2026. In the UK the number is 13%. Average AI expenditures per employee amount to about $2,000 in the US and $725 in the UK, including AI-related expenditures on software, subscriptions to AI services, hardware, worker training, and IT staff support.

Strikingly, there is extremely wide dispersion in AI spending, with the top 2% of UK and US firms accounting for over 50% of total businesses spending on AI. Thus, AI spending appears to be extremely concentrated in just a handful of firms, much more concentrated than say employment or capital expenditures.

Second, four-fifths of survey respondents themselves use AI technologies in the typical working week, with an average use of around 2.1 hours per week by mid-2026. Average weekly use has also increased since the start of the year, when respondents reported using AI around 1.5 hours per week.

Third, more than 80% of executives report that AI has had no effect on employment at their own firms over the past three years. The remaining respondents report small and largely offsetting increases and decreases, implying a near-zero average effect of AI adoption on employment over this period.

Looking ahead, executives expect AI to reduce employment at their own firms by an average of around 0.4% over the next three years. This projected decline is modest and reflects only incumbent firms; employment creation at new firms could offset some or all of it. The small average effect also masks substantial variation across firms: more than 40% expect AI to lead to increases or decreases in employment. Although these anticipated changes largely offset one another at the aggregate level, they suggest that AI could drive considerable job creation and destruction. Hence, AI could reshape the distribution of employment across firms, generating major labor market churn, while leaving overall employment levels broadly unchanged

Fourth, executives report a rising impact of AI adoption on their own firm's labor productivity (sales per employee). Over the last 3-years they estimate that AI-adoption has boosted labor productivity growth by 0.2% a year. This is twice the reported impact (of 0.1%) in our survey run 6 months ago. The share of executives that report no impact of AI on productivity dropped from 89% to 83%, and the share that report positive impacts almost doubled, going from 8% to 15%.

Looking forward over the next 3 years executives anticipate larger future effects on productivity.

They forecast AI will increase annual productivity growth by 0.6% on average, a large impact given average productivity growth of around 1% to 2% in Europe and North America. If correct, these predictions imply a sizable improvement relative to a long period of weak productivity growth in many advanced economies (Bloom et al. 2020, and Goldin et al. 2024). Executives of larger and higher-paying firms anticipate greater productivity gains from AI, as do those in the information, communications, finance, and insurance sectors. Executives from the US, UK, and Canada foresee stronger AI productivity boosts than those in other countries we cover.

Related Literature Our paper relates to four strands of the rapidly growing literature on AI technologies.

First, we build on studies that measure AI adoption. Earlier work yields a wide range of estimates, likely owing to differences in methodology, including survey timing, question wording, sample mix, and respondent characteristics and incentives. Drawing on the 2019 US Annual Business Survey, Acemoglu et al. (2022) and McElheran et al. (2024) estimate that 3% of firms and 13% of firms use AI. Drawing on the US Business Trends and Outlook Survey (BTOS), Bonney et al. (2024) use this to estimate that 5% of businesses (9% employment-weighted) use AI as of February 2024.[3] McKinsey (2025) estimates that 88% of organizations used AI in at least one business function in 2025. Estimated AI adoption rates for the UK also vary widely. According to the Management and Expectations Survey, 9% of firms use AI in 2023 (ONS 2025). An Institute of Directors survey (2025) finds that around 49% of businesses use AI as of 2025, while an LSE-CBI survey finds that 25% of firms had made specific investments in AI technologies by 2024 (Oliveira-Cunha 2024).

We ask business executives about AI usage and its effects at their own firms, a topic on which they have incentives to be well informed. We also lean on long-standing relationships between central banks and business executives, and the desire of executives to maintain them. These features of our approach help us enlist a representative sample of senior business executives who are well positioned to supply informed responses to our survey questions. We use standardized questions across countries and survey waves to allow for comparisons in the cross section and over time.

We contribute to a second literature that measures AI take-up rates across individuals. Bick et al. (2024, 2026), Hartley et al. (2025), Barrero et al. (2025), Sidoti and McClain (2025) and Bloom and

[3] As of December 2025, adoption rates in the BTOS have increased to around 18% of businesses and are expected to rise to 21% over the ensuing six months. See https://www.census.gov/hfp/btos/data

Makridis (2026) all estimate individual AI use at around 30% to 50% of the population. Roughly half of this usage is work-related, and half is for other purposes. Complementing survey-based measures, Iscenko et al. (2026) analyze 15 million interactions across Google's AI products and document broad occupational coverage but shallow penetration, with usage predominantly collaborative rather than involving end-to-end task automation.

A third literature considers the realized and expected impact of AI technologies on businesses and the economy. Some studies find large productivity gains from AI in specific settings. Brynjolfsson et al. (2025a) find that generative AI yields large gains among customer-support agents at a large software firm. Del Rio-Chanona et al. (2025) review several studies that report large gains from generative AI in various settings. Noy and Zhang (2023) conduct an RCT and find that access to ChatGPT boosts productivity in writing assignments.[4] Babina et al. (2024a) link AI investment to product innovation and greater firm value, and Eisfeldt et al. (forthcoming) find a 5% relative value gain at firms with highly AI-exposed workforces in the two weeks after ChatGPT's release. Babina et al. (2024b) develop evidence that AI investments expand firm-level growth options, while Babina et al. (2026) argue that it builds organization capital and raises productivity.

Despite large gains associated with AI in specific tasks and certain firms, the implications for economy-wide productivity are unclear. Adopting a task-based model and applying Hulten's Theorem, Acemoglu (2025) estimates that AI technologies will boost US total factor productivity by at most 0.66% over the next ten years. In sharp contrast, Briggs and Kodnani (2023) estimate that generative AI alone can boost US labor productivity by 1.5 percentage points per year over ten years. Misch et al. (2025), adopting the framework of Acemoglu (2025), estimate that AI will boost TFP in Europe by around 1.1% over five years. Aldasoro et al. (2026) estimate that AI adoption raises labor productivity among European firms by around 4%, with no detectable employment effects.

Finally, we contribute to a literature on the labor market implications of AI. Survey evidence points to modest AI effects to date on overall employment (e.g., Abel et al. 2024, Cañas and Kerr 2024), with larger effects in certain occupations and age groups. Using ADP payroll data, Brynjolfsson et al. (2025b) estimate that generative AI has reduced the relative employment of young Americans (ages 22-25) by 16% in the most AI-exposed occupations, conditional on firm-level shocks. Teutloff et al. (2025) develop evidence that ChatGPT shifted the structure of demand for freelance work, lowering the demand for writing and translation tasks by 20-50% while raising the demand for

[4] Other research finds productivity gains from AI in legal analysis (Choi and Schwarcz 2025), consulting work (Dell'Acqua et al. 2023), and programming (Peng et al. 2023 and Cui et al. 2025)

machine learning programming by 24%. Humlum and Vestergaard (2025) estimate near-zero effects of AI-powered chatbots on earnings and employment at the level of workers and workplaces in Denmark as of 2024.

The next section describes our main data sources. Section 3 validates our data, showing a tight relationship between our survey-based measures and national aggregates. Section 4 presents our results on AI adoption and impact, while Section 5 concludes.

2. Data

This section provides an overview of the seven surveys of business executives we use in our analysis.[5]

We work with central banks and other reputable institutions to reach a representative sample of business executives. A majority of respondents are CEOs, CFOs, or in senior management positions. Our US data come from the Survey of Business Uncertainty (SBU), an economy-wide monthly business survey organized by the Federal Reserve Bank of Atlanta. In the UK, our data are from the Decision Maker Panel (DMP), a monthly, economy-wide survey of UK businesses with ten or more employees run by the Bank of England. In Germany, we use data from the Bundesbank Online Panel of Firms (BOP-F), a quarterly representative survey of firms, run by the Deutsche Bundesbank. In Australia, we use data from the monthly Business Outlook Scenarios Survey (BOSS), fielded by Macquarie University. In Canada, we use data from the Bank of Canada's Business Leaders' Pulse (BLP) survey. In Mexico, we use data from the Monthly Survey on Regional Economic Activity (EMAER) run by the Banco de México. Finally, in South Africa, we use data from the BER/SARB Inflation Expectations Survey organized by the South African Reserve Bank. Below, we provide more detail about each survey and the fielding periods.

Survey Name	Country	Institution	AI Waves

[5] The Bank of Korea also ran a survey that included our main AI questions in June 2026 and received responses from 749 firms. As the survey differed in scope from the other business surveys used in our main analysis, we report these results separately in Appendix C.

Survey of Business Uncertainty (SBU)	USA	Federal Reserve Bank of Atlanta	November 2025; June 2026
Decision Maker Panel (DMP)	UK	Bank of England	February-April 2025; November 2025-January 2026; May-July 2026
Bundesbank Online Panel - Firms (BOP-F)	Germany	Deutsche Bundesbank	January 2026; July 2026
Business Outlook Scenarios Survey (BOSS)	Australia	Macquarie University	December 2025; June 2026
Business Leaders' Pulse	Canada	Bank of Canada	May-June 2026
Monthly Survey on Regional Economic Activity (EMAER)	Mexico	Bank of Mexico	June 2026
Quarterly inflation expectation survey	South Africa	South African Reserve Bank	May 2026

US firms: Survey of Business Uncertainty (SBU)

The Survey of Business Uncertainty (SBU) is a monthly online survey of CEOs, CFOs and senior executives at US firms run by the Federal Reserve Bank of Atlanta.[6] It targets senior managers at a representative sample of firms covering all US regions, industries, and size categories. Respondents are initially recruited by telephone to confirm their position and company, and then moved into the survey panel. The sponsorship of the Atlanta Fed facilitates the recruitment of senior management. Figure 1, Panel A shows that 70% of respondents are CEOs, CFOs or other senior managers while Figure A1 shows the close match of SBU coverage to the population of all US firms, across industries (Panel A) and Census geographic divisions (Panel B).

The SBU was established in 2014, and as of January 2026 receives responses from around 1,000 firms per month. Core survey modules ask each executive about current, past, and future own-firm employment and sales revenue growth. Forward-looking questions elicit subjective probability distributions for these outcomes over the next year. Thus, SBU respondents are accustomed to

[6] https://www.atlantafed.org/research/surveys/business-uncertainty

providing complex forecasts in their survey responses. See Altig et al. (2022) for details and an extended analysis of forecast characteristics and performance.

In addition to the core modules, each monthly edition of the SBU includes special questions on a topic of interest. The November 2025 and June 2026 editions contain several questions on AI adoption and usage intensity, the effects of AI on own-firm employment and productivity in the past three years, and expected own-firm effects of AI over the next three years. For reference, Figure B1 presents screenshots of these questions.[7] The March 2026 edition asked an additional question on AI-related spending (covering software, hardware, subscription services, worker training, and IT support) in 2025 and 2026.[8]

SBU respondents do not receive any monetary or in-kind compensation for joining the panel or completing the surveys. They are motivated to participate to share their views, maintain their relationships with the Federal Reserve System, receive information about the survey results, and perhaps out of a sense of civic responsibility. We view these motivations as a design feature. A challenge with paid online surveys of targeted populations, like senior executives, is that they can generate high impostor shares – as high as 80% according to Chandler and Paolacci (2017). See, also, Bell and Gift (2023). In contrast, in the SBU respondent identities are verified by Atlanta Fed staff.

UK firms: Decision Maker Panel (DMP)

The Decision Maker Panel (DMP) is a monthly, online survey of UK business executives.[9] It is an economy-wide survey and matches the industry and region composition of the UK economy (Appendix Figure A2). Launched in 2016, the Bank of England runs the DMP. Since 2022, the DMP yields about 2,500 survey responses each month. Like the SBU, interviewees are unpaid and are initially recruited by telephone to confirm their position and company, and then moved into the survey panel. Sponsorship by the Bank of England facilitates the recruitment of senior executives. Over 90% of respondents are either CFOs, CEOs, or in other senior management positions (Figure 1, Panel B).

Each month the DMP asks senior executives about the evolution of sales, prices, employment, wages, and capital expenditures at their firm over the past year and expectations for the year ahead.

[7] Screenshots of the survey questions from all the surveys are available on the project website: https://firmdataai.com/
[8] A summary of the main results is available here: https://www.atlantafed.org/research-and-data/publications/policy-hub-macroblog/2026/05/06/how-much-firms-spending-on-ai-and-what-will-happen-to-headcounts
[9] https://decisionmakerpanel.co.uk/

In addition to these standard questions, the DMP regularly includes special questions on topical issues. For further information, see Bunn et al. (2024) who provide a detailed overview of the survey, including the structure, quality checks against other datasets, and information on how to access the data.

Several DMP editions include questions about the adoption of AI technologies and the impact of AI on their employment and sales per employee (a proxy for productivity). In addition, survey respondents were asked how frequently they personally use AI technologies during the work week. We focus on data collected from November 2025 to January 2026 and May to July 2026, which overlap with the fielding period for several of the other surveys. But the DMP also collected data on AI adoption between February and April 2025, which adds one additional data point in the time series dimension.

We match DMP data with firm-level financials in the Bureau van Dijk (BvD) database, which contains basic accounts and directors data for UK companies.[10] BvD is based on the population of UK firms in Companies House.

German firms: Bundesbank Online Panel – Firms (BOP-F)

The Bundesbank Online Panel – Firms (BOP-F) is an online survey of a representative panel of firms located in Germany and is run by the Deutsche Bundesbank – Germany's central bank. The survey was first conducted in June 2020 and since July 2021, it surveys around 8,000-9,000 CEOs and CFOs in German-registered companies per quarter.

The sample for the BOP-F survey is drawn from the Business Register, with the sponsorship of the Bundesbank supporting the recruitment of senior executives. Firms from nearly all economic sectors with more than 12,500 EUR annual turnover or at least one employee who also provided information on their full address are eligible (see Boddin et al. 2024 for more information on how the sample is drawn).

While the survey has a quarterly frequency from the firm's perspective, new responses are collected every month, with the questionnaire being in the field for about three weeks. This is because the survey follows the rotating panel principle, whereby one third of all new firms in the sample are randomly selected into group A, B, or C, with only one group being surveyed per month.

[10] Figure A3 shows a strong relationship between survey data in the DMP on employment and sales to matched annual company accounts data from BvD, which is indicative of high-quality survey responses.

In January 2026, questions on adoption of AI technologies, impacts of AI on employment and productivity, and the average weekly use of AI by the survey respondent were asked in the BOP-F based on the SBU and DMP questions, with responses from around 2,500 firms. The questions on adoption of AI technologies and average weekly use of AI were also asked in July 2026 and received responses from around 2,300 businesses.

Australian firms: Business Outlook Scenarios Survey (BOSS)

The Business Outlook Scenarios Survey (BOSS) is a monthly, online survey of Australian businesses.[11] The BOSS targets senior financial decision makers at a representative sample of firms over all Australian locations and industries, with 87% being either CFOs, CEOs, or in senior management positions, and was established in 2024 by Macquarie University.

Each month BOSS surveys more than 500 businesses on their one-year-ahead expectations of key macroeconomic variables such as inflation and interest rate, as well as the evolution of key business indicators such as growth rates of sales, prices of their own products and services, employment, wages and operating cost.

The questions on AI adoption, realized and expected impacts on productivity and employment, and personal use by the survey respondent were added to the BOSS survey and administered between 1 and 8 December 2025, with 602 firms participating in the survey. The questions were asked again in June 2026 and received responses from around 900 firms.

Canadian firms: Business Leaders' Pulse (BLP)

The Business Leaders' Pulse (BLP) is a monthly online survey of businesses in Canada run by the Bank of Canada (see Chernis et al. 2022 for further details). The panel is designed to be informative for assessing aggregate economic conditions relevant to Canadian gross domestic product (GDP). Established in 2021, the BLP collects responses from around 800 or more firms each month.

The BLP gathers information from Canadian business leaders on a range of topics, including sales, current business conditions, employment, inflation expectations and investment intentions. Each month, a subset of participating firms is also asked topical questions that address specific information needs of the Bank.

[11] https://www.mq.edu.au/macquarie-business-school/our-departments/department-of-economics/our-research/business-outlook-scenarios-survey-boss

Questions on adoption of AI technologies, impacts of AI on employment and productivity, and average weekly use of AI by the survey respondent were asked in the BLP over May and June 2026. The Canadian results are based on approximately 900 survey responses, except for questions on labor productivity, which were asked to a subset of roughly 600 firms.

Mexican firms: Monthly Survey on Regional Economic Activity (EMAER)

The Monthly Survey on Regional Economic Activity (EMAER, for its name in Spanish) is a representative survey of establishments with more than 100 workers in the manufacturing and non-manufacturing sectors at both the regional and national levels in Mexico. It collects the perceptions of managers of large firms regarding the performance of their businesses and their short-term expectations. The survey was first implemented in March 2009 for the manufacturing sector and has covered the non-manufacturing sectors since November 2010.

The EMAER is conducted monthly, generally beginning on the first day of each month, and has an approximate duration of four weeks. Responses are submitted electronically through an online platform designed specifically for the survey. Businesses whose responses are delayed are contacted and may also provide their responses by telephone. Respondents do not receive any monetary or in-kind compensation for participating in the survey. Since 2025, Banco de México has collected responses from an average of 1,670 firms per month, while ensuring that the responses meet the representativeness requirements for each region and sector.

In addition to its recurring monthly modules, which collect information on the retrospective and prospective evolution of firms' economic indicators and on inflation expectations, the survey includes special modules that change every month. These modules collect timely information on specific economic circumstances that become particularly relevant at different points in time. Questions on AI adoption, realized and expected impacts on productivity and employment, and personal use of AI by the survey respondent were included in the EMAER in June 2026 and received responses from 1,719 firms.

South African firms: Quarterly inflation expectation survey

The Bureau for Economic Research has conducted a quarterly inflation expectations survey on behalf of the South African Reserve Bank since the adoption of inflation targeting in 2000.[12] The survey was initially administered through a combination of online and paper-based questionnaires submitted by post. However, since the COVID-19 pandemic, it has been conducted entirely online.

[12] https://www.ber.ac.za/Documents/Index/Inflation-Expectations

Among the groups surveyed are South African firms, which provide expectations for inflation alongside a range of other macroeconomic indicators, including GDP growth and wages. In May 2026, 96% of the firm survey respondents were CFOs or CEOs. While the survey sample size has decreased to around 120 respondents in the last few years due to falling response rates, Reid et al. (2026) recently confirmed that the sample was still representative in terms of firm size, region, and industrial sector in 2024.

The questions on AI adoption, personal AI use, and its impacts on productivity and employment were included in the May 2026 inflation expectations survey and 121 firms responded.

3. Data Validation

To validate the quality of our firm survey panels before showing our AI data we run two exercises.

First, in Figure 2 we show how 10 years of data on output and employment from our firm panels compare against aggregate data for the US SBU and UK DMP surveys. Output data from the US survey tracks US GDP growth (top-left) and private employment (top-right), as do UK data when compared to UK GDP growth (bottom-left) and private sector employment (bottom-right). Hence, our surveys are accurate and representative of macro aggregates over the past decade. Their performance is similar across the pre-pandemic period, the COVID recession and recovery, and post-pandemic stabilization. Hence, we are confident that, due to our large representative sample of senior executives, our data reflect aggregate trends across the business cycle.

Second, we show the performance of the sales and employment forecasting questions included in our surveys on a quarterly basis. Once a quarter, executives are asked to forecast their year-ahead (12 months ahead) sales growth and employment growth. One year later we compare these forecasts to actual realizations of sales and employment growth for these firms. This enables a large sample evaluation of our survey respondents' forecast accuracy. As we see in Figure 3, our responding executives make accurate forecasts, with sales and employment predictions lining up tightly with realizations occurring over the next year. This positive relationship suggests that our panel is well-equipped to predict the future business conditions for their firms, increasing our confidence in the accuracy of their forecasts of the impact of AI.

4. Main Results

We present the overall results which combine firm-level results from each country into one figure, and also provide country-level values. Tables can also be downloaded from https://bit.ly/4B2zU5c

4.1 Current and expected use of AI technologies

We begin by analyzing the current use of AI technologies by businesses. In all seven surveys, firms are asked to select which of the following they are currently using, if any: data processing using machine learning; visual content creation; Generative AI; image processing using machine learning; robotics and autonomous vehicles; or other. Firms could select more than one technology.

Figure 4A presents the main results. The black bars in the figure correspond to the average use across firms in all seven surveys, weighted by the sample sizes of the respective surveys. Across all seven countries, we find that a majority of businesses are currently using some AI technology. Adoption is highest in the US (95% of firms), followed by the UK (88%), Canada (82%), Germany (78%), Australia (68%), Mexico (64%), and South Africa (56%). On average, 78% of all firms are currently using AI.

Figure 4B shows that adoption is not concentrated in a single use case. The most popular current use is 'Generative AI' (by 63% of firms on average), but 34% of firms also report using visual content creation and 33% use data processing using machine learning. Less commonly cited uses were image processing using machine learning (22%), and robotics and autonomous vehicles (8% of firms), which are likely more specific to certain industries.

Adoption of AI technologies has increased since the start of 2026. Figure A4 compares the trends in AI adoption over the available survey waves. Current use of AI technologies increased across all four countries in the original sample. In the US, adoption is near-universal, with around 95% of businesses using at least one AI technology even at the start of the year.[13] In the UK, adoption has also increased further since February-April 2025, when the questions were asked for the first time. This emphasizes the importance of having consistency in the timing of the questions across data sources during a time when adoption is increasing rapidly across businesses.

We next study the characteristics of firms which predict the current use of AI technologies. In Figure A5.a, we present a series of binned scatter plots of the relationships between current use of AI (on the vertical axes) and a series of firm characteristics. This figure uses data from the DMP survey, due to the larger sample size and the availability of more firm covariates.[14] We find that more

[13] In the first version of the paper, the percentage of US businesses using any AI technology was 78%. In that calculation, firms which skipped the question on use of AI technologies were treated as non-users rather than missing. In the current draft, we treat firms that skip the questions as missing observations, which increases the AI adoption to 94% in November 2025 and 95% in June 2026.

[14] In Figure A5.b, we show similar results for a subset of variables from the US SBU. More productive (Panel A) and larger (Panel B) firms are more likely to be using an AI technology in US firms as well.

productive (Panel A), larger (Panel B), and higher-paying firms (Panel C) are more likely to be using AI.[15] In contrast, in Panels D and E, we show that firms with older directors on average, and older firms are *less* likely to be currently using AI. Use of AI technologies also varies by sector. In Figure A6 Panel A, we show that current AI adoption by UK firms is highest in the finance and insurance and information and communications sectors.

In Table 1, we test the robustness of these relationships in a regression table where we combine all the variables in a single specification and also control for industry and time fixed effects. The dependent variable in Columns 1-2 is a dummy for whether a firm uses any AI technology, scaled by 100 for interpretability. We find that the most robust predictors of AI use from Figure A5.a are firm employment, average wage per employee, and the average age of directors.[16]

Measures of firm AI adoption vary widely across recently published studies, especially those drawing on survey data. We highlight three features of survey design which can partly account for these gaps, and illustrate them using data from the UK Decision Maker Panel. The first is the composition of the sample across firm size categories. Consistent with the results above, larger firms are more likely to use AI: 80% of firms with 10-49 employees currently use at least one AI technology, rising to 83% among firms with 50-99 employees, 87% among firms with 100-249 employees, and 92% among firms with 250 or more employees (Figure A7, Panel A). Surveys which over-sample larger businesses, or which exclude the smallest firms altogether, will therefore report higher adoption rates than surveys which do not. Table A1 presents the breakdown of survey responses by firm size category across the seven surveys in our main dataset. The second is the choice of weighting scheme, which follows directly from this size gradient. Panel B of Figure A7 shows that current AI use among UK firms is 88% when responses are weighted by employment, 86% when unweighted, and 83% when weighted by the number of businesses in each industry and size band. Employment weighting places more weight on the large, AI-intensive firms, while business-count weighting places more weight on the small firms which dominate the firm population, generating a spread of five percentage points from identical underlying responses. The third is the position of the survey respondent within the business. Panel C shows that adoption is

[15] Labor productivity is constructed using firm-level accounts data from BvD as the real gross value-added per employee. The data from the latest accounts available for each firm are used in the figure. The average wage per employee (Panel C) is constructed as the total wage bill per employee, again using accounts data.

[16] We do not include a regression of productivity growth, real sales growth, and employment growth in the same specification because productivity growth is defined in our analysis as real sales growth – employment growth. Running these three variables in the same specification would result in collinearity. Therefore, we split the results into two columns.

89% when the respondent is a CEO or CFO, compared with 84% when the respondent holds any other position.

We examine this last difference further in Table A2, which regresses our indicator for current AI use on a dummy for whether the respondent is a CEO or CFO. The gap does not appear to be driven by the types of firms that senior executives run. Respondents in these roles report adoption rates four to seven percentage points higher than other respondents, and the estimated difference remains statistically significant and stable in specifications controlling for firm size, labor productivity, firm age, the average age of directors, and industry and time fixed effects. Two interpretations are consistent with this pattern. CEOs and CFOs may have a more complete view of AI use across their organization, in which case surveys of more junior respondents understate true adoption; alternatively, senior executives may be more willing to report AI use that they do not directly observe, in which case surveys of executives overstate it. Either way, comparisons of adoption rates across surveys should take account of who is answering the questionnaire. Taken together, these three factors each move measured adoption by between five and twelve percentage points, and they compound: a survey of small firms, weighted by business counts and answered by non-executives, will report substantially lower adoption than one of large firms, weighted by employment and answered by CEOs. They therefore narrow the range of estimates in the literature without closing it. Differences in question wording and in survey timing remain important additional explanations for differences in AI adoption measures.

Finally, we consider how firms expect adoption of AI technologies to change over the next three years. Figure A8.1 shows that AI adoption is expected to increase on average. Across all seven countries, 82% of firms expect to be using some AI technology over the next three years. Furthermore, we find that the most common technology firms expect to use is data processing using machine learning (Figure A8.2), suggesting firms are expecting to build capacity to use AI tools for data processing, even if they are not currently used as extensively.[17] Expected AI adoption has also been trending up over time (Figure A8.3), having increased in all four countries sampled in the beginning of the year.

4.2 Firm Spending on AI

To complement the results on the use of different AI technologies, in the US and UK, additional questions were asked in 2026 about AI-related spending in the 2025 and 2026 calendar years. AI-

[17] AI adoption is also expected to increase across almost all industries over the next 3 years (Figure A6, Panel B).

related spending captures software, subscription services, hardware, worker training, and IT staff support, and provides a quantitative measure of the *intensity* of AI adoption. Figure 5 presents distributions of these results across five categories. We scale AI spending by firm employment and convert the UK results into US dollars for comparability. Panel A shows the results for the US, where firms spent around $1,363 per employee in 2025 and expect to spend $2,043 per employee in 2026 (employment-weighted). Over 80% of firms were spending on AI in 2025, and 23% were spending more than $1,000 per employee. For 2026, only 11% of firms expect not to make any AI-related spending. But this spending is very skewed, with 55.7% of the total in firms spending $10,000 or more, and the top 10% of firms accounting for 90% of all spending, with an average spend of $7,480 per employee each. Total US AI spending based on these numbers aggregates up to an overall spend of about $280 billion on AI across the entire US economy. Table 2 shows the AI spending per employee in both 2025 and 2026 for different percentiles of the distribution.

Panel B of Figure 5 shows the results for UK firms in the DMP. A larger share (33% of firms) did not make AI-related expenditures in 2025, but this is expected to drop sharply to 17% in 2026. Meanwhile, increases are expected in AI-spending between $100 to $999 per employee (29% to 44%) and in firms spending more than $1,000 per employee (8% to 13%). Based on these responses, we estimate that UK firms spent $422 per employee on AI-related expenditures in 2025 and this is expected to increase to $725 per employee in 2026. Again, like the US this spending is very skewed, with 30% of the total in firms spending $10,000 or more in 2026, and the top 10% of firms accounting for 69% of all spending with an average spend of $5,200 per employee each. Total UK AI spending based on these numbers aggregates up to an overall spend of about $25 billion on AI across the entire UK economy in 2026.

The firm characteristics that are highly correlated with AI adoption are also highly correlated with AI spending per employee. In Figure A9, we present five binned scatterplots of AI spending per employee in 2026 against the same characteristics used in Figure A5.a. This figure is based on data collected for UK firms over August-September 2026. More productive (Panel A) and higher-paying firms (Panel C) spend significantly more on AI per employee in 2026; we also find that AI spending is higher at younger firms (Panel E) and firms with younger directors (Panel D). Larger firms spend less *per employee* (Panel B), although they spend more in aggregate terms. In Columns 3-4 of Table 1, we test how robust these relationships are in multivariate regressions that also control for industry and time fixed effects. Higher-paying firms spend significantly more on AI per employee. We also find that firms that expect higher productivity growth and higher real sales growth in 2026 spend more on AI.

Figure 6 provides further evidence that AI spending is highly concentrated across firms. This figure plots the cumulative share of *total* AI spending in 2026 against the cumulative share of firms.[18] In both the US and the UK, the curves indicate that a small share of firms accounts for a very large share of aggregate expenditure. Specifically, 1.8% of US firms and 1.3% of UK firms account for 50% of all AI spending in 2026 in the respective countries. This is consistent with evidence from AI producing firms: Anthropic's IPO documents showed that one-quarter of its sales are to two firms.[19] Similarly, the AI spending Gini coefficient for 2026 is 0.92 in the UK and 0.9 in the US, materially higher than income Gini coefficients in the two countries.[20]

Overall, these two sections highlight that AI use is widespread across businesses in seven countries sampled. Larger and more productive firms are more likely to be using AI technologies, as are higher-paying businesses. AI adoption has increased since the start of 2026 and is expected to increase over the coming years. But this spending is extremely skewed across firms, with the top 10% of firms accounting for 90% and 69% of spending in the US and UK, respectively. In Sections 4.4 and 4.5, we present new evidence on how firms estimate that AI has been impacting their employment and productivity, and how they expect these effects to change in the next three years.

4.3 Use of AI by survey respondents

In this section, we analyze how frequently respondents themselves use AI during a typical work week. As these respondents typically hold senior positions in their firms (e.g. CEOs, CFOs, senior finance managers), these results are another useful proxy for AI adoption more broadly since they are in a position to instruct their subordinates to make use of AI as they see the opportunity. They are also less likely to be subject to measurement error, as the respondents are reporting about their personal use, rather than for the business as a whole. The survey asks whether they personally use AI technologies: "Not at all"; "Up to 1 hour a week"; "1 to 5 hours a week"; or "More than 5 hours a week".

In Figure 7A, we assign quantitative values to each of the categories to estimate the average number of hours of AI use. Across all firms, our respondents use AI around 2.1 hours per week on average. These results are similar across the seven countries, ranging from 1.7 hours in Mexico to 2.5 hours

[18] In Figure A10 we present a similar figure for the distribution of cumulative AI spending *per employee* across firms. We again find a very skewed distribution, with less than 5% of firms accounting for 50% of all AI spending per employee in 2026.
[19] See 'Anthropic warns of 'existential risks to humanity' in IPO prospectus, Financial Times, 29 September 2026
[20] The latest data from the World Bank estimate an income Gini coefficient of 0.42 for the US in 2024 and 0.32 in the UK in 2021. https://data.worldbank.org/indicator/SI.POV.GINI

in the US and Canada. Figure 7B presents the distribution of responses across the four categories. Across all firms, 21% of respondents do not use AI at all during the working week. The modal response is up to 1 hour a week (35%), but more intensive AI use is not uncommon. 30% of respondents report 1-5 hours of AI use per week, and 13% report using AI more than five hours in a typical working week. The use of AI by survey respondents has also been increasing steadily over time (Figure A11), from around 1.5 hours a week on average in the beginning of the year. In the UK, the average use has more than doubled since the February-April 2025 wave.

We next consider how AI use varies with firm-level and respondent characteristics. Figure A12.a presents binned scatterplots with the average weekly AI use on the vertical axis for UK firms. We find that respondents in younger firms use AI technologies more often during the working week (Panel A), as do respondents in firms where the average age of directors is lower (Panel B). These relationships are similar to Figure A5.a, Panels D and E, where the firm age and average age of directors are shown to be negatively correlated with current AI adoption across the business.[21] Figure A12.b shows that a similar negative relationship is present between firm age and average weekly AI use in US firms. In Figure A13 we split the frequency of AI use by the position of the respondent in the business. Specifically, we distinguish between CEOs, CFOs, and other senior executives. In both the US (Panel A) and UK (Panel B), we find that AI is more frequently used by CEOs than other respondents.

4.4 Impact of AI on firm employment

In this section we present the results on the impact of AI technologies on firm realized and expected employment. For the US, UK, Canada, Mexico, Australia, and South Africa we use the latest data collected in mid-2026. German firms were not asked this question in the latest survey; for Germany, we instead refer to the results from January 2026. Firms are asked to estimate the employment impacts using five categories, ranging from a large positive impact (increasing employment by more than 5%) to a large negative impact (decreasing employment by more than 5%). To estimate an average quantitative impact of AI on employment, we assign numerical values to each of the five categories. We assign values $\pm 7.5\%$ to large positive/negative impacts; $\pm 2.5\%$ to small positive/negative impacts; and 0% to no impact.

[21] In Columns 5-6 of Table 1 we analyze the determinants of weekly AI use. We find that the average wage per employee and average age of directors remains the most significant predictor of average weekly AI use.

In Figure 8A we present these average impacts. Across all firms, the impact of AI is essentially zero over the past three years. However, there is some heterogeneity across the seven countries. In the UK and South Africa firms report small negative effects, on average, of around -0.1% over the past three years. Meanwhile, in the US, Canada, Germany, and Mexico, firms report small positive effects, ranging from +0.1% to +0.2%. Australian firms report an impact around zero. Figure 8B shows the distribution of responses across the five categories. Across the seven surveys, 87% of firms on average estimate no impact over the last three years. This percentage varied somewhat across countries: Germany (95%), US, Canada, and the UK (88% of firms), South Africa (82%), Mexico (80%), and Australia (74%). Finally, Figure A14 plots the estimated impacts of AI on employment over survey waves. There is no clear trend in the series, suggesting the employment effects have not changed over time.

There is substantial sectoral heterogeneity in the realized employment impacts of AI. Figure A15, Panel A shows the average realized employment impacts from AI across industries in the UK. The impacts vary from positive in the Real estate sector (+0.3%) to negative in the Wholesale and retail (-0.2%) and Recreational services (-0.4%) sectors.

Turning to the next three years, in Figure 9A we present the quantitative estimates of the expected employment impacts of AI. On average, firms across the seven countries expect AI to lower employment by around 0.4% over the next three years. Even this projection of a modest negative employment impact is too pessimistic for three reasons. First, our forward-looking survey data don't capture the positive general equilibrium effects of AI-driven productivity gains on aggregate employment. Second, our survey forecasts miss net job gains by firms not yet born. Third, our sample frames underrepresent the youngest firms. If AI advances have relatively positive effects on employment at younger firms, we undercount those gains as well. In short, the key message is that our survey evidence suggests that AI technologies will not have large effects on aggregate employment in the next three years.

Looking at individual countries the largest effects are in the UK and the US (both -1.3%). Australian firms expect AI to lower employment by around 0.5%, and Canadian and German firms expect only a 0.1% employment decline. At the same time, Mexican firms expect a small employment boost due to AI of around 0.6% over the next three years, and South African firms expect a small increase of around 0.1%.

Figure 9B shows the distribution of responses across the five categories. Here the results are much more striking with a wide range of responses, and over 40% of firms reporting that AI will impact

employment either positively or negatively. This highlights that while AI may not impact overall employment it looks likely to generate considerable churn across firms, with large movements of employment across firms. Finally, Figure A16 shows how these expected employment impacts have changed over time. In the UK and US, there has not been a significant change since the beginning of the year, with estimated impacts ranging from -1.2% to -1.3%. The expected employment impacts in Australia have become more negative, from around zero in the beginning of the year to -0.5% in mid-2026.

There remains heterogeneity across sectors in the expected employment impacts, as we show in Figure A15, Panel B. The expected impacts over the next three years are negative across all sectors of the economy for firms in the UK. The largest negative impacts are in the Wholesale and retail (-1.7%), Professional and scientific (-1.7%), and Finance and insurance (-1.9%) sectors.

Beyond the sectoral differences, we also consider how the expected employment impacts vary with various firm-level characteristics. Columns 7-8 of Table 1 present the covariates of expected AI employment impacts for UK firms. To maximize the sample size, the regressions use the latest firm observation on the expected employment impact using data collected over February-April 2025, November 2025-January 2026, and May-July 2026. We find that larger firms expect more negative impacts of AI on employment.[22] In contrast, higher realized employment growth in 2025 and higher expected employment growth in 2025 are both associated with *less* negative AI employment impacts.[23]

4.5 Impact of AI on firm productivity

In this section we present results on the impact of AI technologies on firms' realized and expected productivity. The survey questions follow the same structure as the employment impacts. Productivity in this analysis is defined as the volume of sales per employee. These questions were included in the mid-2026 waves in all surveys except Germany; for Germany, we use earlier data from January 2026 in the figures below.

Figure 10A presents the main results on realized productivity impacts over the past three years. To

[22] Expected employment impacts are also more negative among firms whose survey respondent personally uses AI more intensively, ranging from -0.7% where the respondent reports no personal use to -2.2% where they use AI for more than five hours per week (Figure A17).

[23] One concern is that firms expecting more negative employment impacts from AI are simply more pessimistic about their employment prospects in general. To assess this, we relate expected AI employment impacts to firms' employment growth forecast errors. Figure A18 shows no systematic relationship for both forecast errors (Panel A) and absolute employment growth forecast errors (Panel B). Thus, firms that habitually over- or under-predict their own employment growth do not report systematically different impacts of AI.

estimate an average quantitative impact of AI on productivity, we assign numerical values to each of the five categories. As with the employment impact, we assign values $\pm 7.5\%$ to large positive/negative impacts; $\pm 2.5\%$ to small positive/negative impacts; and *0%* to no impact. Across all firms, AI is reported to have boosted productivity by around 0.5% over the past three years. The effects are very similar across the US, Canada, UK, Germany, and Australia, ranging from +0.2% to +0.5%. Mexican firms report slightly larger productivity gains, at +0.7% over the past three years, on average. Figure A19**,** Panel A shows a breakdown of the realized AI productivity impacts by industry for UK firms. These are positive across all industries in the UK. Firms in the Information and Communications and Professional and Scientific sectors report the largest positive productivity impacts from AI so far, at +1.3% and +1%, respectively.

In Figure 10B, we show the distribution of responses across the five categories. Across the seven surveys, 83% of firms on average estimate no impact over the last three years. This percentage is highest in Germany (91%), followed by Canada (85% of firms), South Africa (84%), the US (83%), the UK and Australia (82% in both), and Mexico (75%). Among the remaining firms which report some impact, the results are decisively skewed to the positive across all seven countries, indicating some positive impacts in the aggregate. Finally, Figure A20 shows how the realized AI productivity impacts have changed since past survey waves. The estimated impacts have increased in both the UK and US since the start of 2026, from 0.2-0.3% to 0.5% in mid-2026. The impacts have remained about 0.5% in Australia.

In Figure 11A, we present results on how firms expect AI to impact their productivity over the next three years. Over the next three years, firms across the seven countries expect AI to increase labor productivity by an average of around 1.7%, implying an increase in annual productivity growth of about 0.6%. The largest expected effects are in the UK (+2.6%), the US (+2.3%), Canada (+2%), and Mexico (+1.9%). Smaller, but still positive and significant effects are expected in Germany (+0.9%), Australia (+0.7%) and South Africa (+0.6%).

Figure 11B shows the distribution of these responses across the five categories. 53% of all firms expect no impact over the next three years, with the distribution of responses being clearly skewed to the positive. 27% of all firms expect a small positive impact, increasing productivity by less than 5%, and 16% expect a large positive impact on productivity, greater than 5%. Figure A21 shows how the expected productivity impacts have changed over time. UK firms expect even larger productivity gains than at the beginning of 2026, rising from 1.9% to 2.6%. US firms now expect a 2.3% productivity boost, compared with 2.2% in the beginning of the year. Expected productivity

gains among Australian firms have declined slightly, from 0.9% to 0.7% in the latest data.

The productivity boost from AI is not expected to be equally distributed across sectors of the economy, as we show in Figure A19**,** Panel B**.** Based on data from the UK, the largest impacts are in the information and communications sector, which expects AI to increase productivity by 4.4%. The finance and insurance, real estate, and professional and scientific sectors also expect large gains, at around 3.4% over the next three years. Much smaller impacts are expected by firms in construction, recreational services, and other production (which include agriculture and mining and quarrying).

As with the expected employment impacts, we also consider how the expected productivity impacts vary with various firm-level characteristics. Table 1, Columns 9-10 present the covariates of expected AI productivity impacts using multivariate regressions for UK firms.[24] As was the case for employment, the regressions use the latest firm observation on the expected productivity impact using data collected over February-April 2025, November 2025-January 2026, and May-July 2026 which gives 3,215 unique firm observations. We find that larger firms, firms with younger directors, and those with higher expected real sales growth have more positive expected impacts of AI on productivity.[25]

To quantify the potential aggregate productivity effects of AI adoption, we combine estimated impacts of AI on firms' sales per employee and employment from the DMP with UK national accounts aggregates and data on AI-related expenditures. We use the latest DMP estimates that AI increased sales per employee by 0.54% and reduced employment by 0.1% over the past three years, and will increase sales per employee by 2.6% while reducing employment by 1.3% over the next three years. AI expenditure is assumed to average £313 per worker per year over the past three years and £537 per worker per year over the next three years, based on data collected from the DMP over August-September 2026. In the accounting framework, AI expenditure is treated primarily as an additional intermediate input, with a small proportion contributing to the capital stock. Under these assumptions, AI is estimated to have raised sales per employee growth by around 0.18 percentage points per year over the past three years and to raise it by a *further* 0.69 percentage points per year

[24] Expected productivity impacts are also larger among firms whose survey respondent personally uses AI more intensively, rising from +1.1% where the respondent reports no personal use to +3.9% where they use AI for more than five hours per week (Figure A22). Together with Figure A17, this suggests respondents with more direct experience of AI anticipate both larger productivity gains and larger displacement, rather than simply holding a more favorable view of the technology.

[25] Similar to Figure A18, in Figure A23 we find no systematic relationship between expected AI productivity impacts and firms' sales growth forecast errors. Expectations of larger productivity impacts from AI are not associated with firms' general forecasting optimism.

over the next three years (Table 3). Because additional AI expenditure increases intermediate input costs, the implied impact on gross value added (GVA) per worker is smaller, amounting to around 0.17 percentage points per year over the past three years. Over the next 3 years, the reduction in employment compensates and the impact on labor productivity is estimated at +0.85 percentage points per year over the next three years. Lastly, applying a standard growth-accounting decomposition with labor and capital shares of 0.67 and 0.33, respectively, implies corresponding contributions to total factor productivity (TFP) growth of approximately +0.13 percentage points per year over the past three years and +0.68 percentage points per year over the next three years.

Finally, we examine how expected employment and productivity impacts relate to one another within firms. Because we define productivity as the volume of sales per employee, a firm expecting to hold output constant and reduce employment would report an expected productivity gain exactly equal in magnitude to its expected employment reduction. Figure A24 presents a binned scatter plot of expected employment impacts against expected productivity impacts, controlling for industry and time fixed effects. The relationship is negative and statistically significant, but the slope is well below one in absolute value (-0.07): firms anticipating larger productivity gains from AI expect only modestly larger reductions in employment. Firms therefore expect a substantial share of the productivity gains from AI to arrive through higher output rather than lower headcount.

Overall, the last two sections show that the adoption of AI technologies has had little impact on firm employment and a small positive impact on firm productivity so far. However, firms anticipate large impacts over the next few years. On average, businesses expect AI to boost productivity by around 1.7% over the next three years, while lowering employment by around 0.4% over the same period. This also implies an increase in output of around 1.3% (Table 4). A limitation of our analysis is that we cannot assess how AI affects employment across different groups of workers. For example, a decline in employment among younger workers could be offset by an increase among older workers, leaving little change in a firm's total employment.

5. Conclusion

Drawing on our original surveys of nearly 9,000 senior business executives, we present new evidence on how firms and the executives use AI technologies, and on the past and expected future effects of AI advances on employment, productivity, and AI-related spending in the US, Canada, the UK, Germany, Australia, Mexico and South Africa. We put our questions to executives from November 2025 to January 2026 and again from May to July 2026.

We obtain several findings. First, 78% of businesses use some form of AI technologies as of May-June 2026, and adoption is expected to increase. Larger, more productive, and higher-paying firms are more likely to use AI technologies. Second, US executives expect AI spending per employee to reach $2,000 per employee in 2026, 50% more than in 2025. Third, this spending is highly concentrated with 2% of firms accounting for over half of $300 billion in aggregate AI spending. Fourth, senior business executives use AI tools about 2.1 hours per week on average, as of May-July 2026, up from 1.5 hours at the start of 2026. Fifth, our survey evidence AI has had little employment impact to date as of mid-2026. In contrast, the same executives estimate that AI has increased labor productivity by around 0.5% over the past three years. Sixth, these executives anticipate larger AI-driven productivity gains of about 1.7% over the next three years. Seventh, combining our survey evidence with basic economic reasoning suggests that AI technologies will have little impact on aggregate employment over the next three years but may materially boost the extent of job creation and destruction.

We will continue our efforts to survey senior business executives across many countries in cooperation with central banks and other leading institutions. Our goal is to monitor the adoption of AI technologies over time, the spending on AI-related investments and activities, and the (perceived) effects of AI technologies on employment, productivity, and other outcomes.

Figure 1 Position of respondents within their firm

Panel A US Firms (SBU)

Panel B UK Firms (DMP)

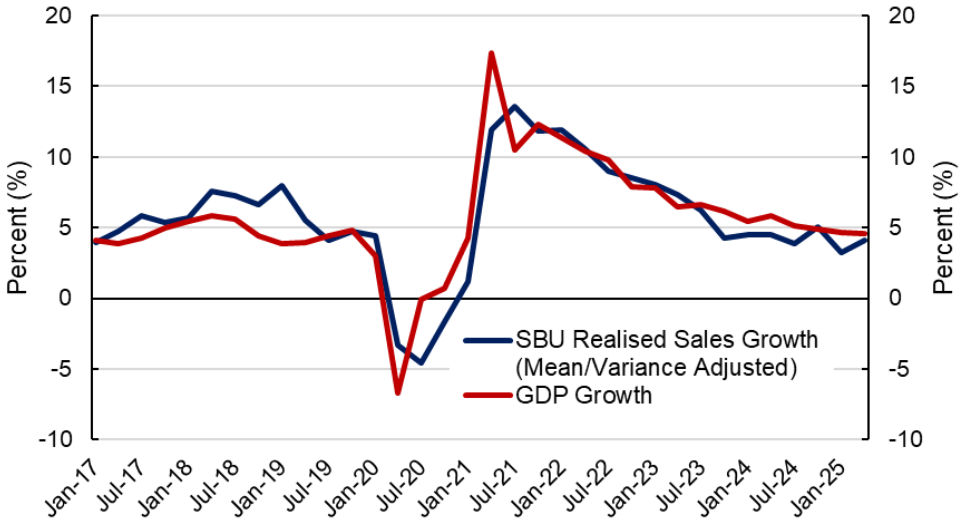

***Notes**: This figure shows the position of survey respondents. Panel A shows data from the US Survey of Business Uncertainty (SBU), averaged over January 2017 to January 2025. Panel B shows data from the UK Decision Maker Panel (DMP), averaged over 2017-2025.*

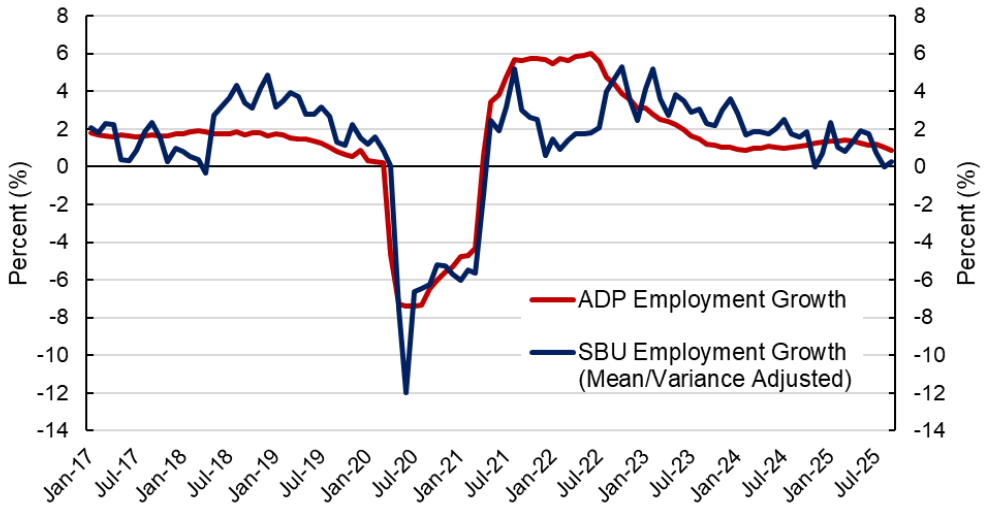

Figure 2 Firm sales and employment growth vs aggregate statistics

Panel A Sales growth

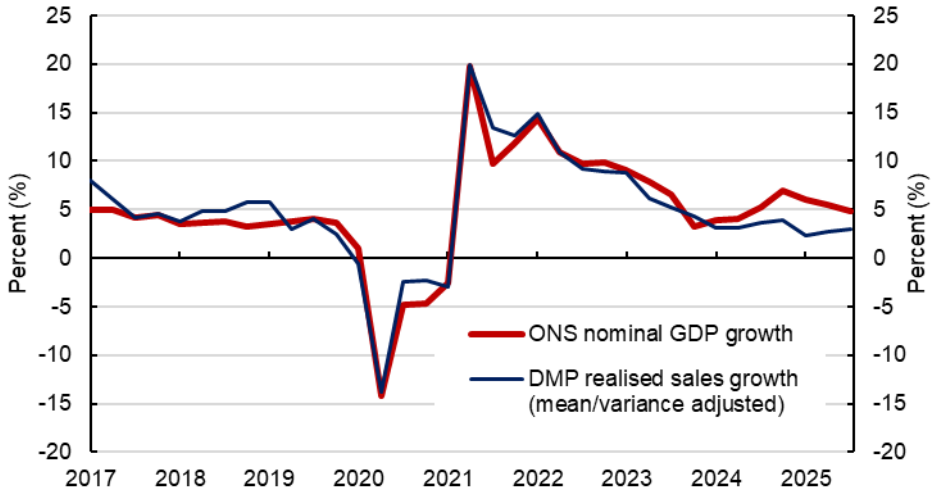

Panel B Employment growth

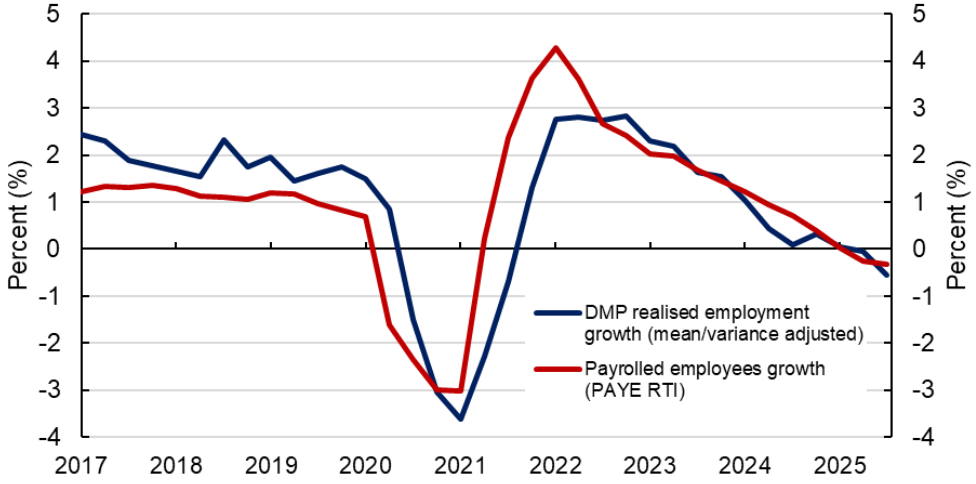

US Firms (SBU)

UK Firms (DMP)

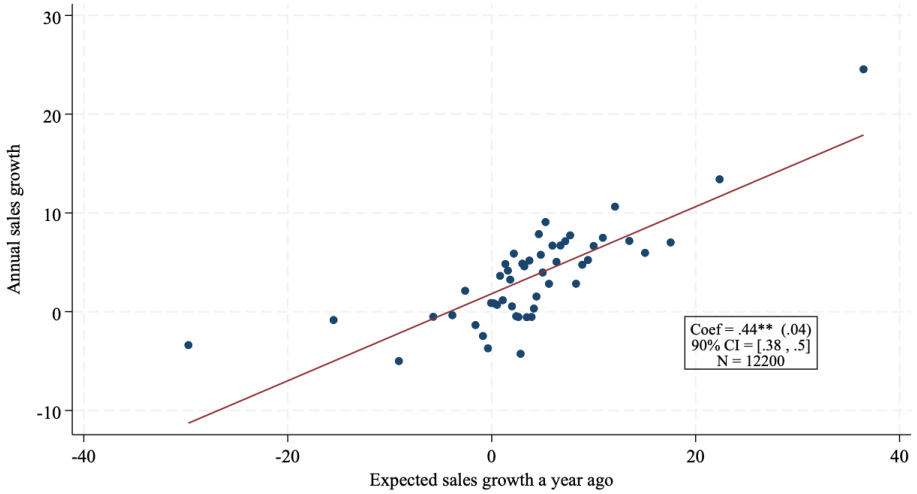

***Sources**: SBU; ADP; BEA; DMP; ONS; HMRS and authors' calculations. **Notes**: SBU sales data are compared to GDP growth from the BEA. SBU employment growth data are compared to ADP employment growth. DMP sales data are compared to whole economy nominal GDP growth at current market prices. DMP employment (for the private sector) is compared to ONS/HMRC data on the number of payrolled employees. DMP and SBU data are adjusted to match the mean and variance of growth in the corresponding ONS, HMRC, GDP, and ADP series over the time period shown on each chart.*

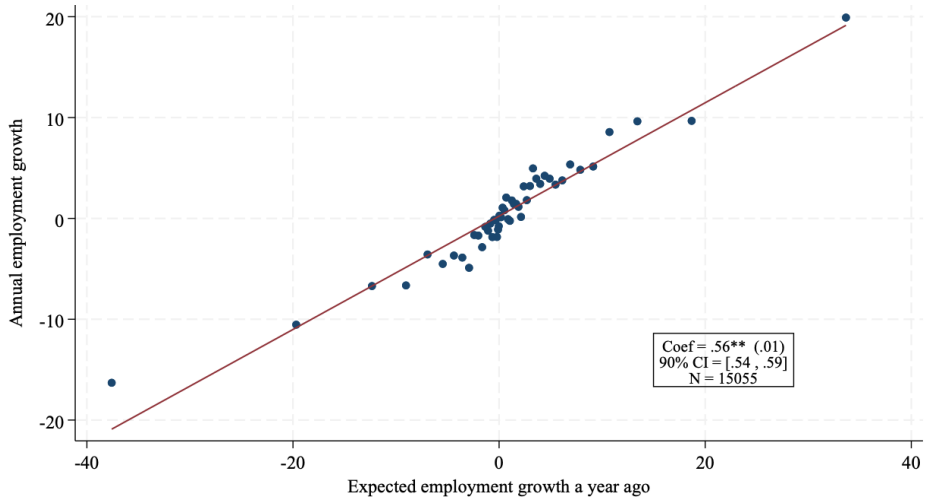

Figure 3 Sales and Employment Forecasts vs Realizations

Panel A Sales growth

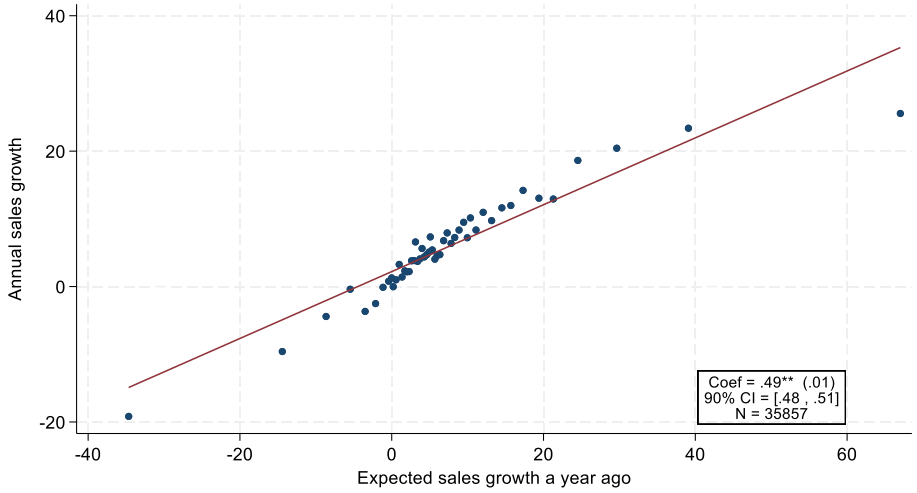

Panel B Employment growth

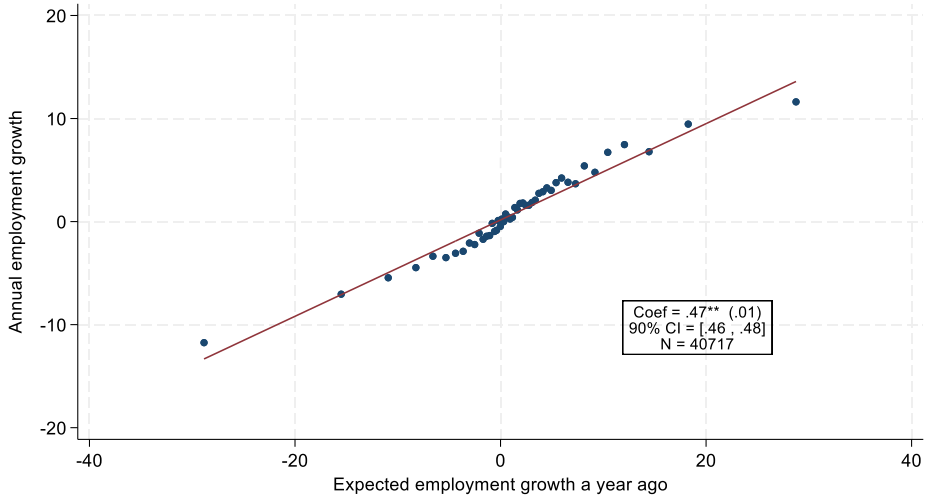

US Firms (SBU)

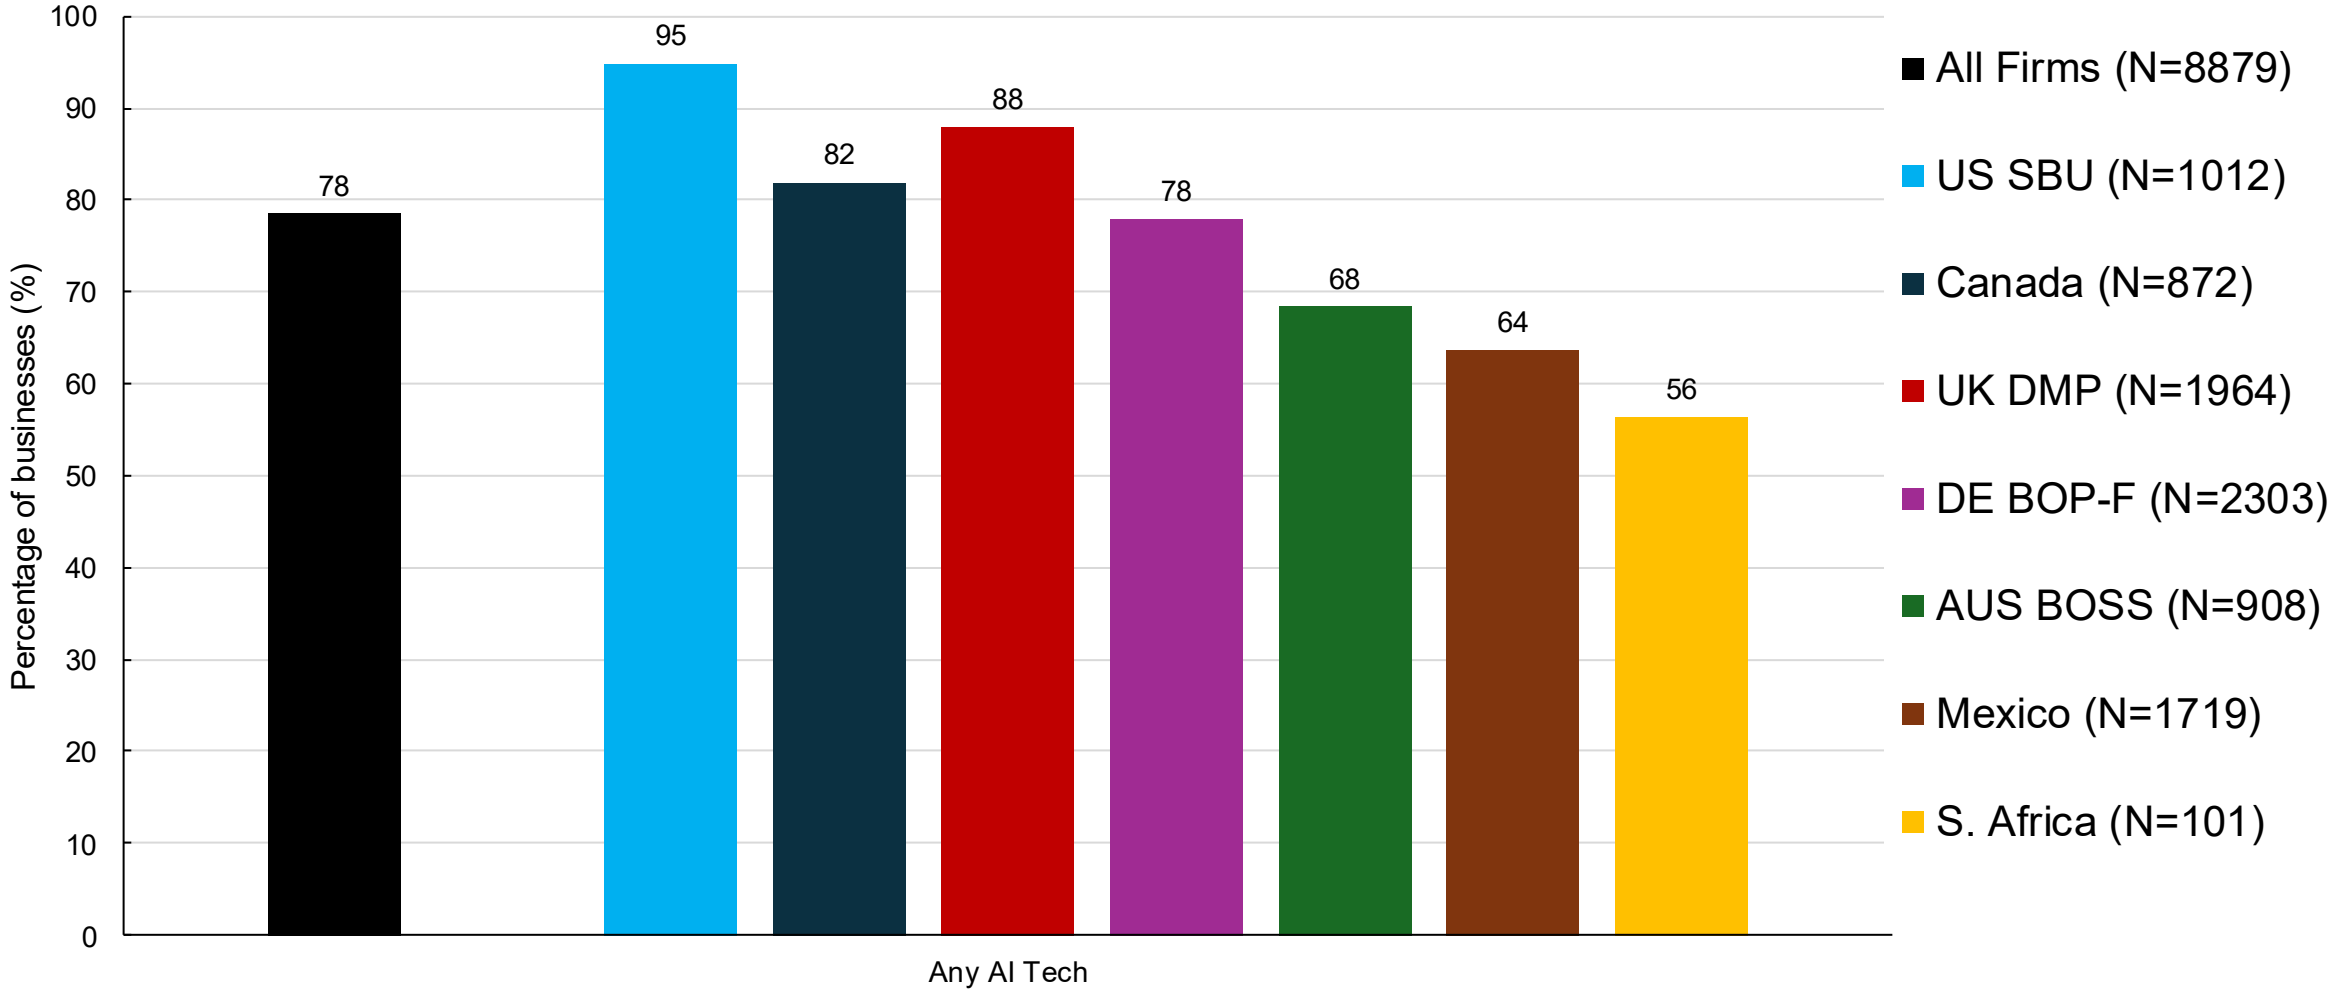

UK Firms (DMP)

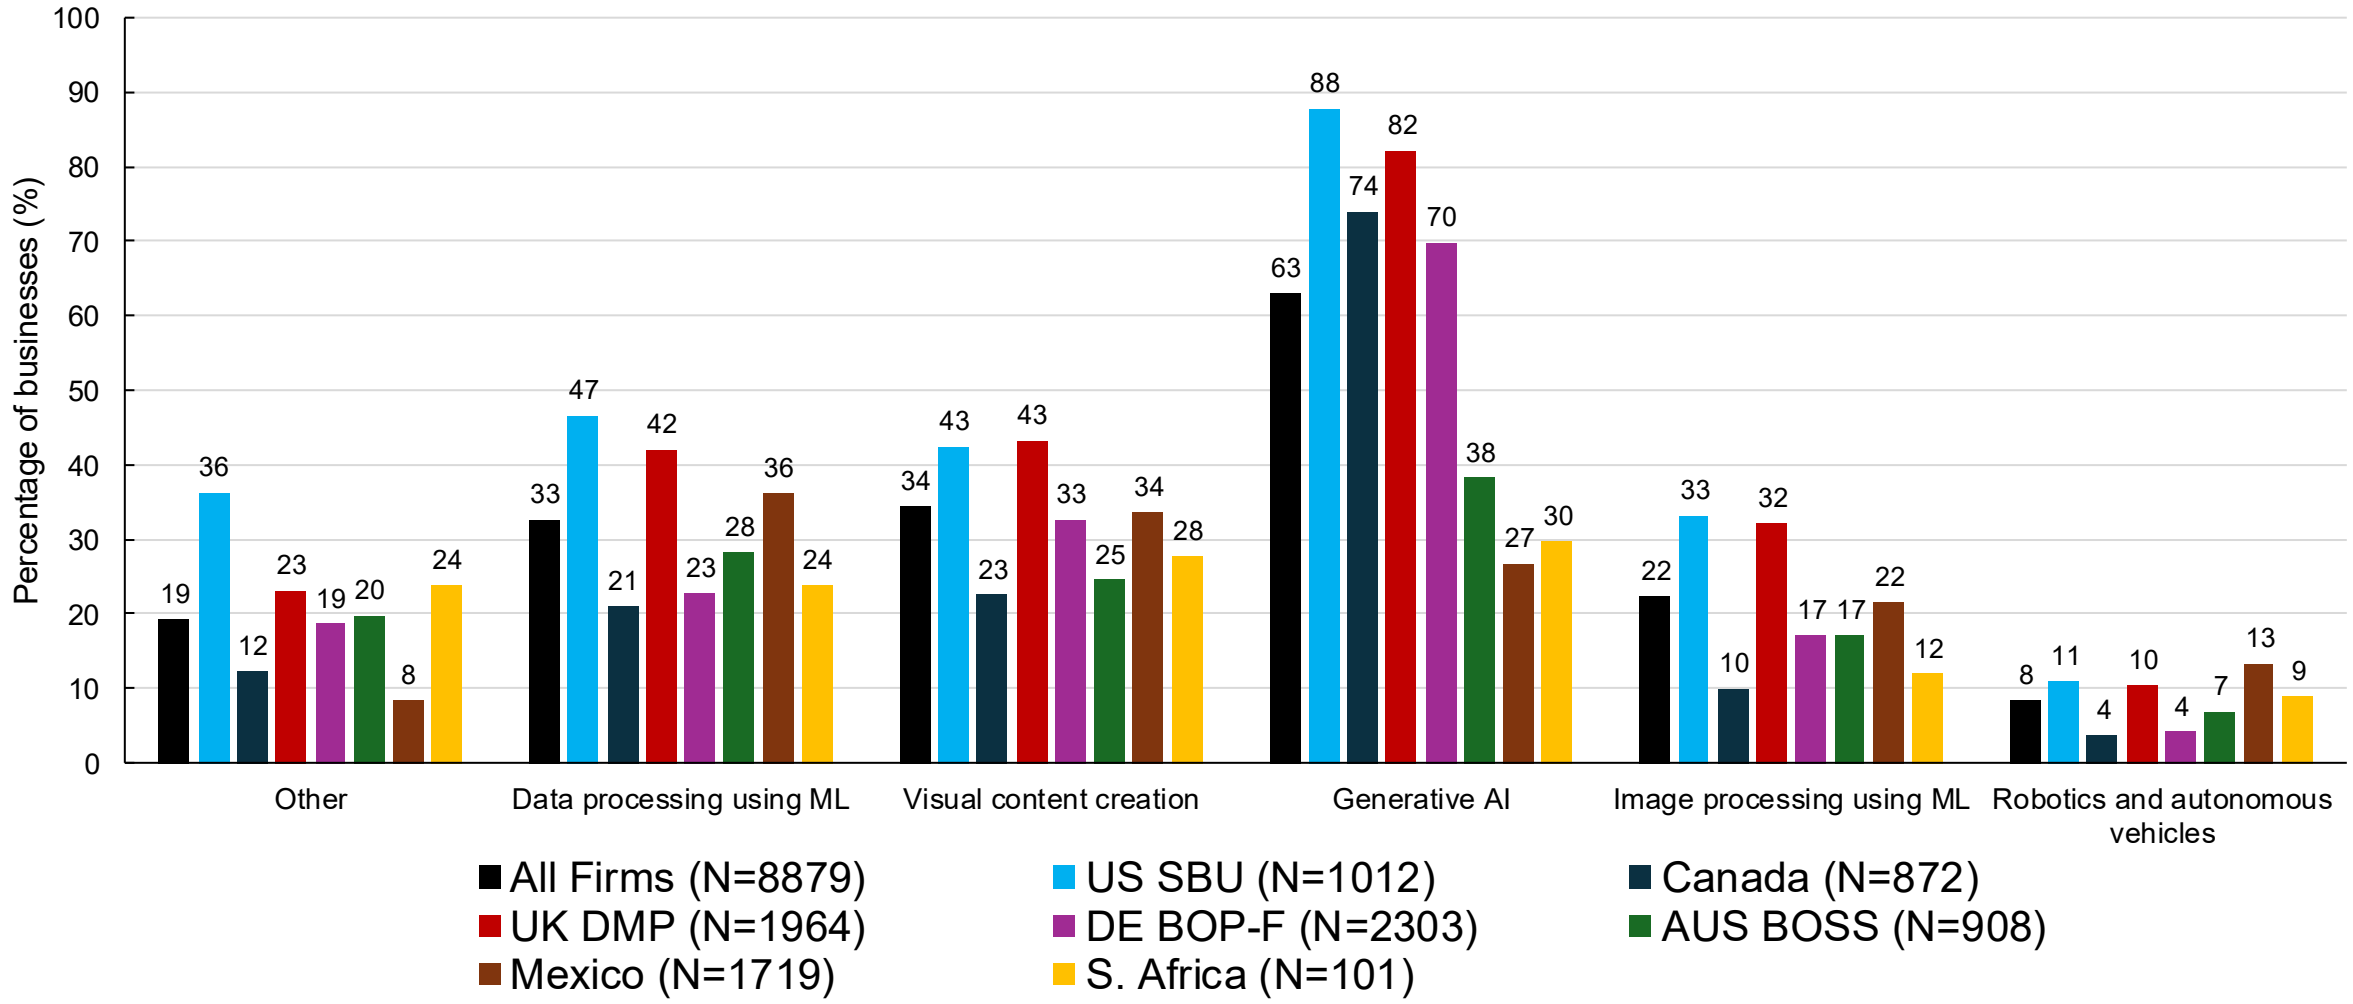

***Notes**: This figure shows binned scatter plots of the relationship between expected year-ahead sales growth and annual sales growth a year later at the firm level (Panel A) and expected year-ahead employment growth and annual employment growth a year later (Panel B). The sample from the SBU covers 2014-2025. The sample from the UK DMP covers 2017-2025.*

Figure 4A Current use of AI technologies by businesses

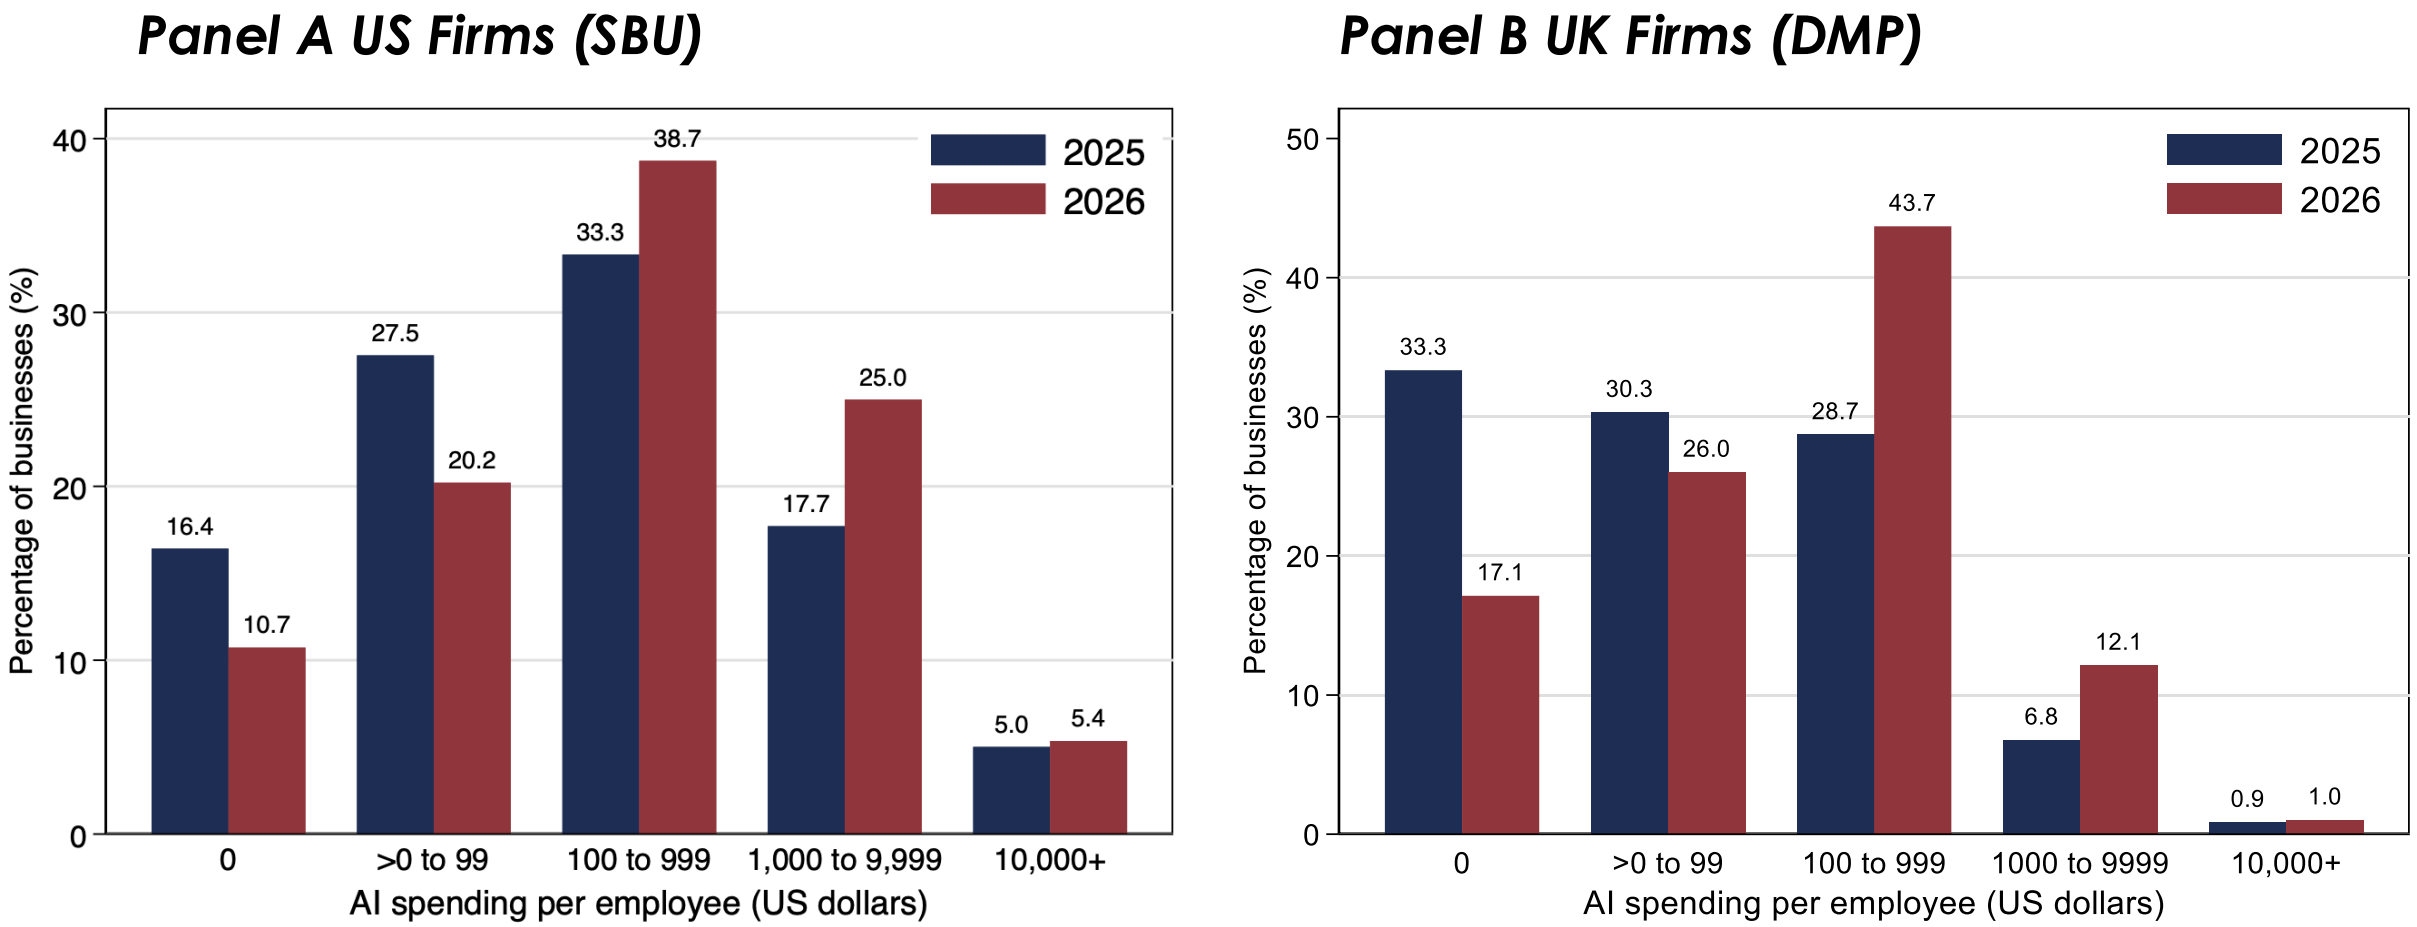

***Notes**: This figure is based on responses to the question: "Which of the following artificial intelligence technologies, if any, does your business currently use?" Firms could select more than one option. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The data for all seven countries was collected over May to July 2026. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 4B Current use of AI technologies by businesses

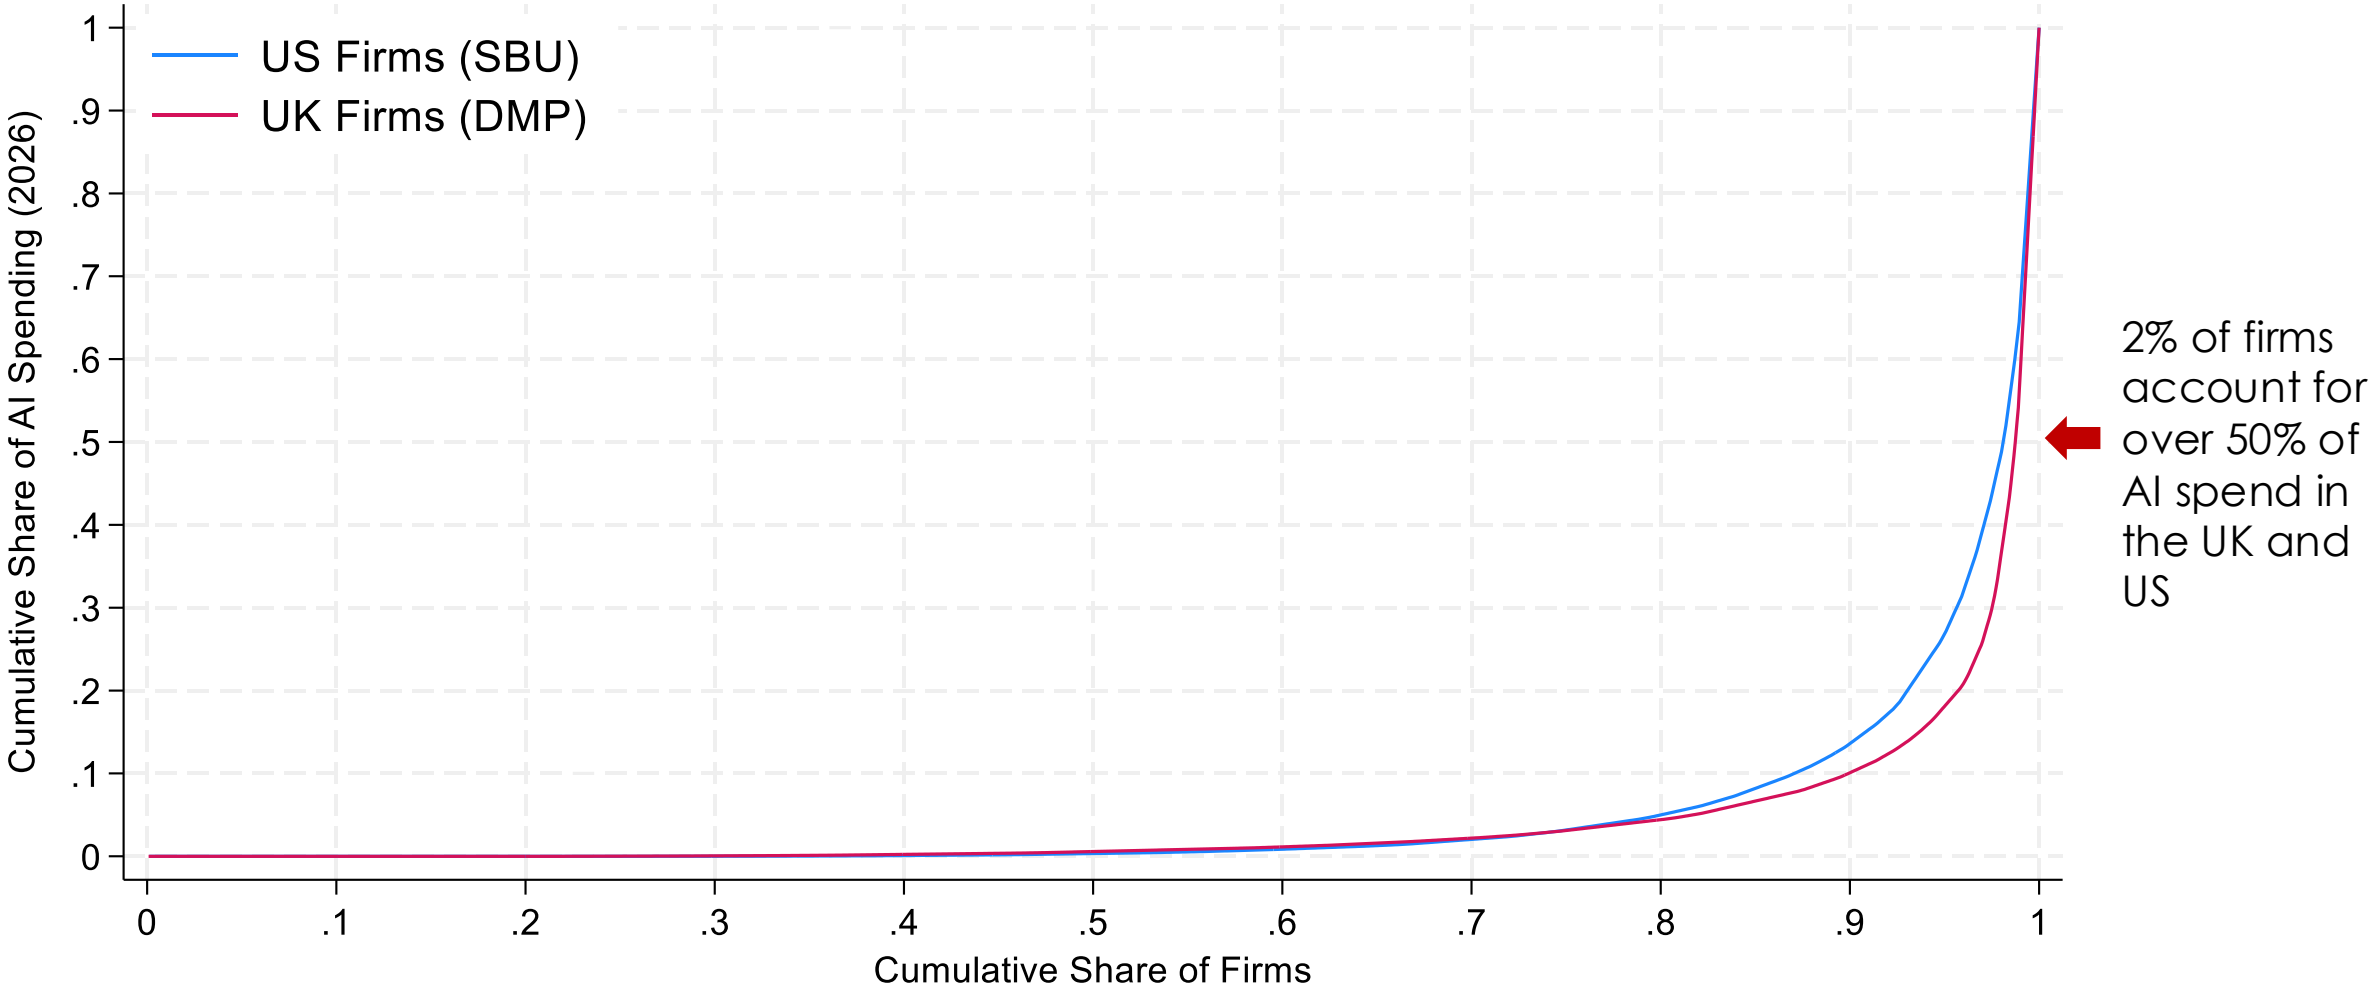

***Notes**: This figure is based on responses to the question: "Which of the following artificial intelligence technologies, if any, does your business currently use?" Firms could select more than one option. The data for all seven countries was collected over May to July 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 5 AI Spending per Employee

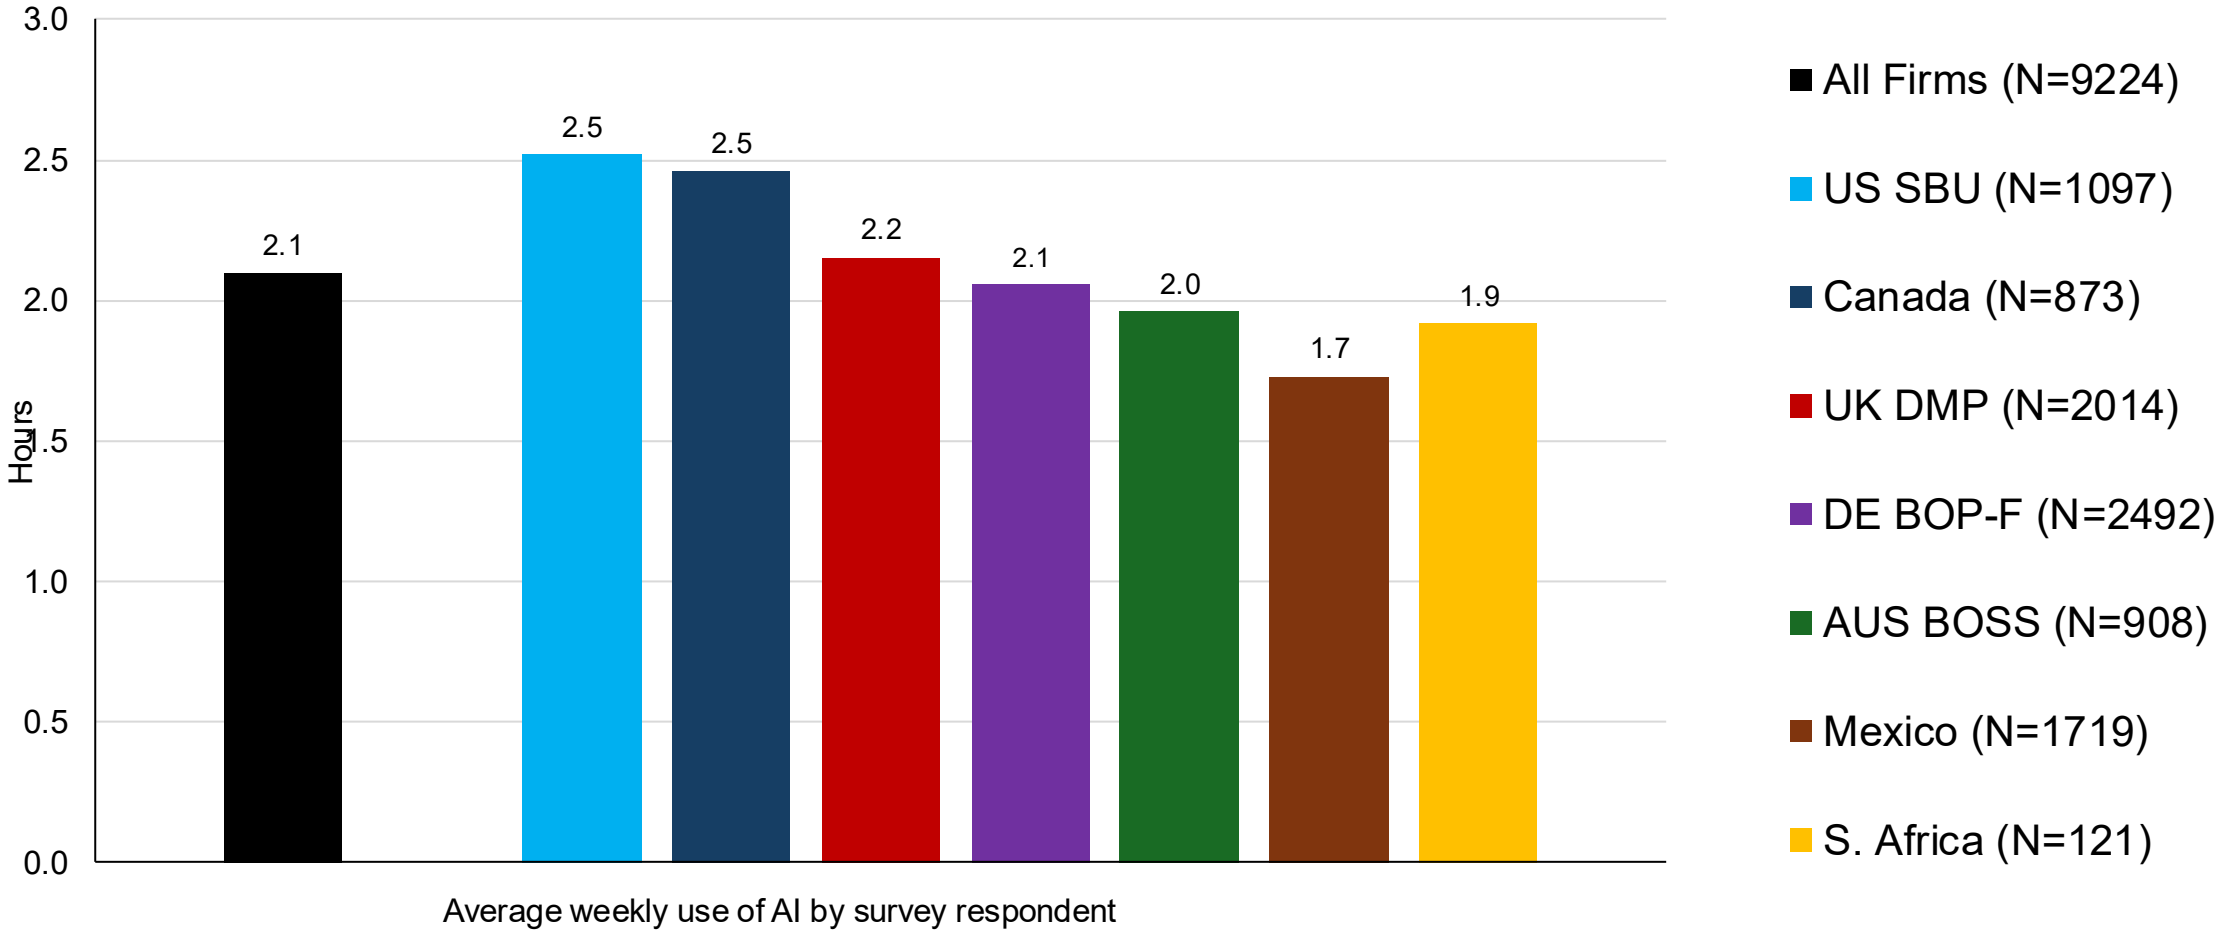

***Notes**: Respondents were asked to answer the following two question: (1) Thinking back to last year (calendar year 2025), approximately how much did your firm spend on artificial intelligence adoption and AI related technologies? Include software, subscription services, hardware, worker training and IT staff support. (2) Now think about this year. For calendar year 2026, approximately how much do you expect your firm will spend on artificial intelligence adoption and AI related technologies? Include software, subscription services, hardware, worker training and IT staff support. Panel is based on 845 responses from firms in the US Survey of Business Uncertainty in March 2026. Panel B is based on 1273 responses to the Decision Maker Panel in August-September 2026. Original responses in Panel B are in GBP and converted to USD using exchange rate of 1.35 $/£"*

Figure 6 Firm AI spending is highly skewed

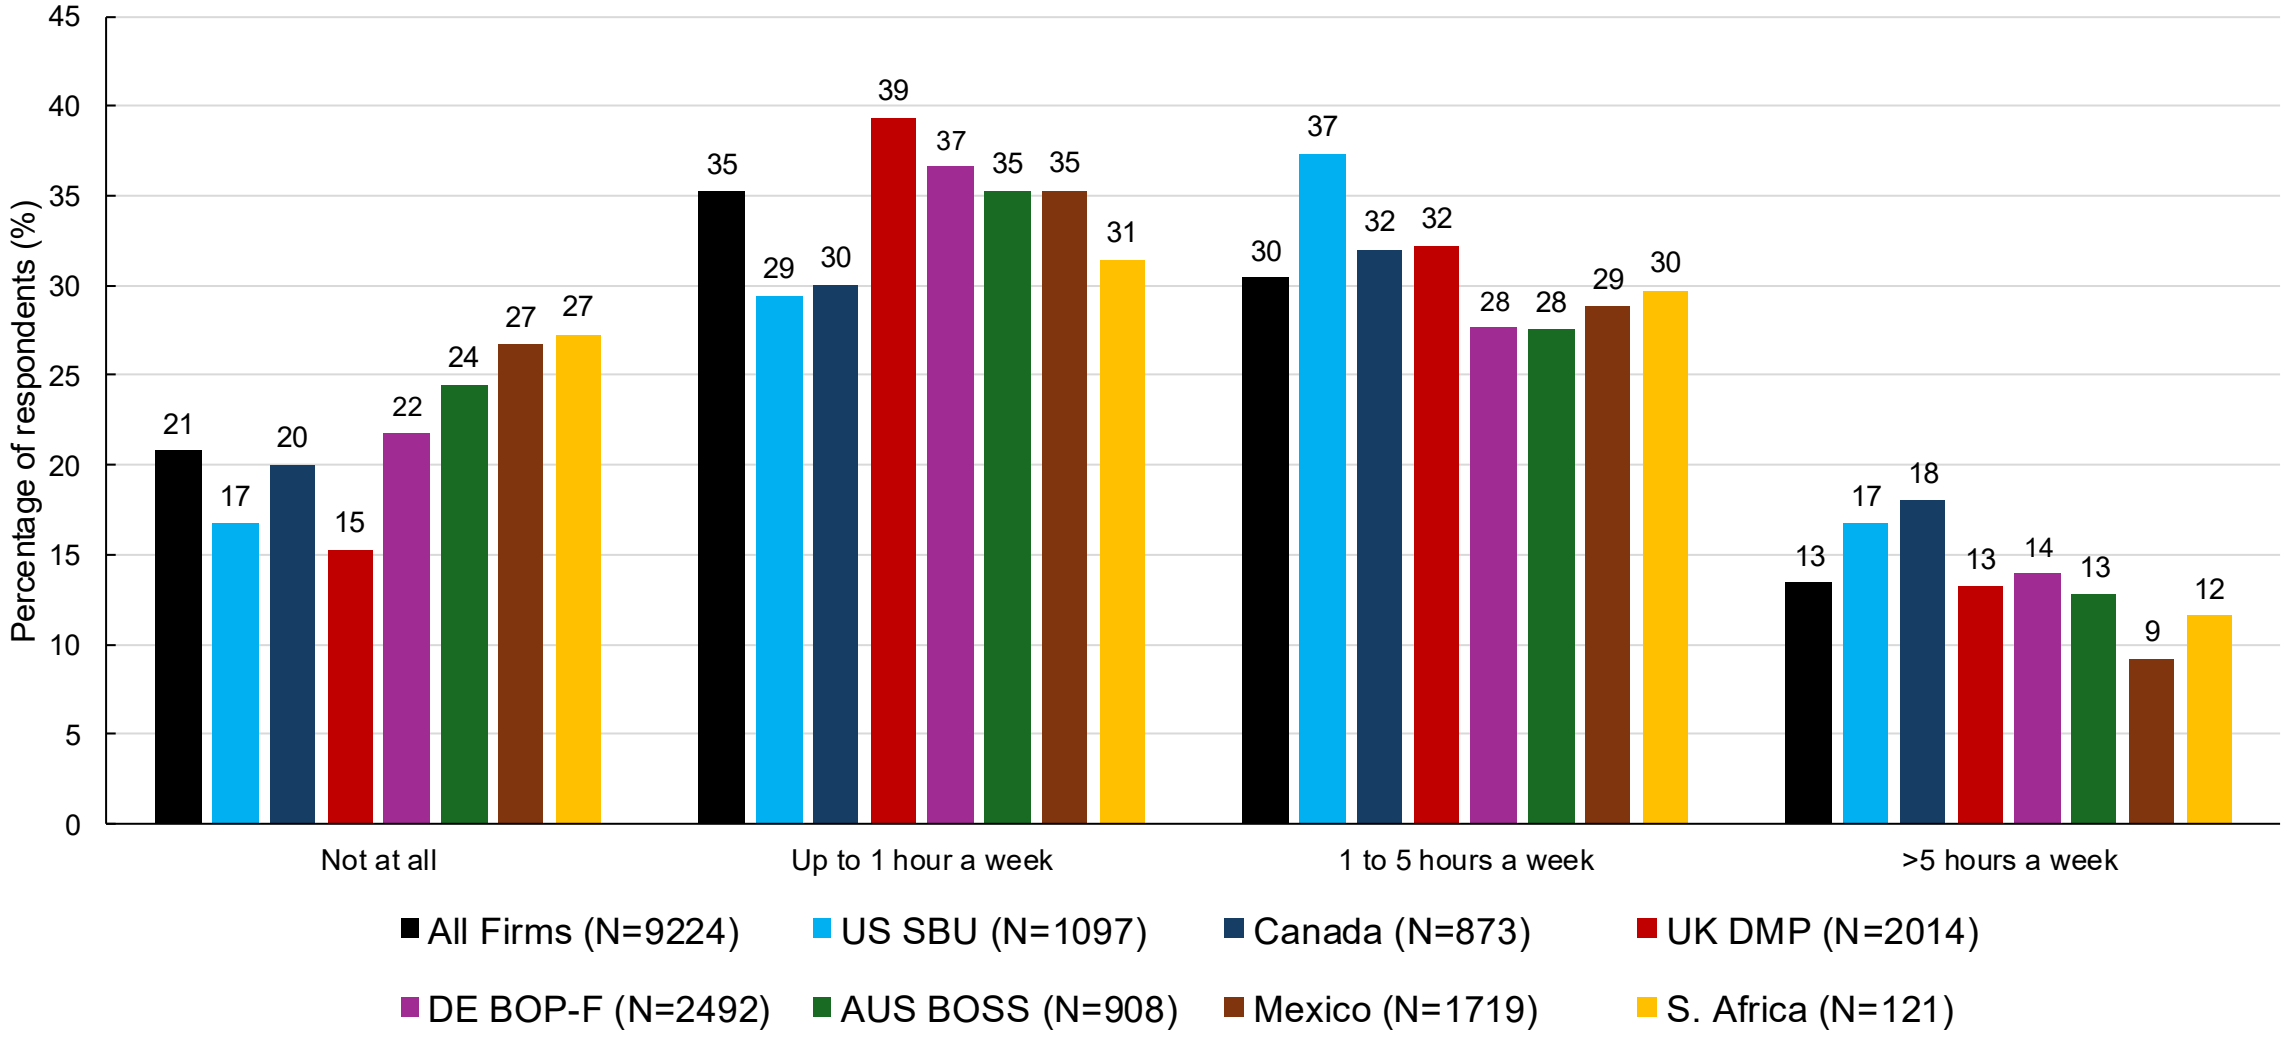

***Notes**: This figure is based on responses to the question: For calendar year 2026, approximately how much do you expect your firm will spend on artificial intelligence adoption and AI related technologies? Include software, subscription services, hardware, worker training and IT staff support. The results are based on 845 responses from firms in the US Survey of Business Uncertainty in March 2026 and 1,273 responses to the Decision Maker Panel in August-September 2026.*

Figure 7A Frequency of AI use by survey respondent

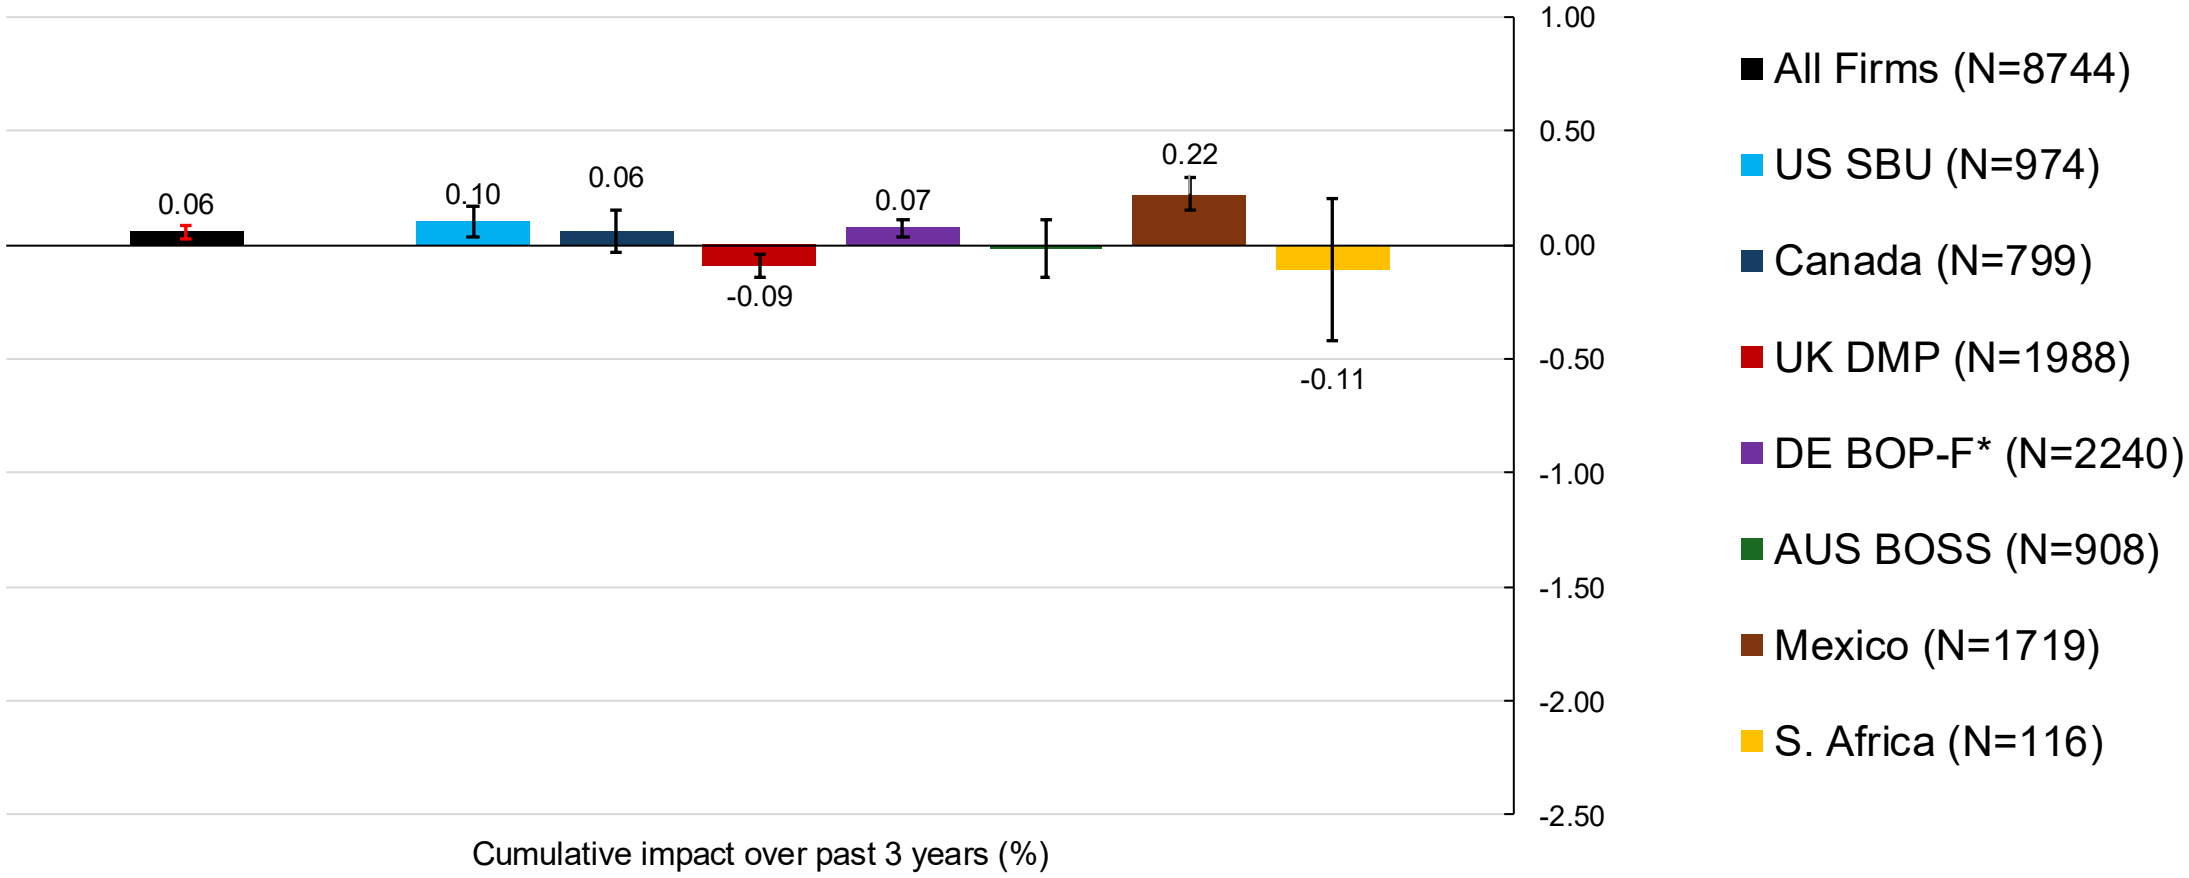

***Notes**: This figure is based on responses to the question: "On average, how frequently do you personally use artificial intelligence technologies in a typical working week?" The results for all firms is the average of the seven surveys, weighted by the respective number of responses. To calculate the average use per week, values are assigned to each of the options: 0 to "Not at all"; 0.5 to "up to 1 hour a week"; 3 to "1 to 5 hours a week"; 7.5 to ">5 hours a week". The data for all seven countries was collected over May to July 2026. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 7B Frequency of AI use by survey respondent

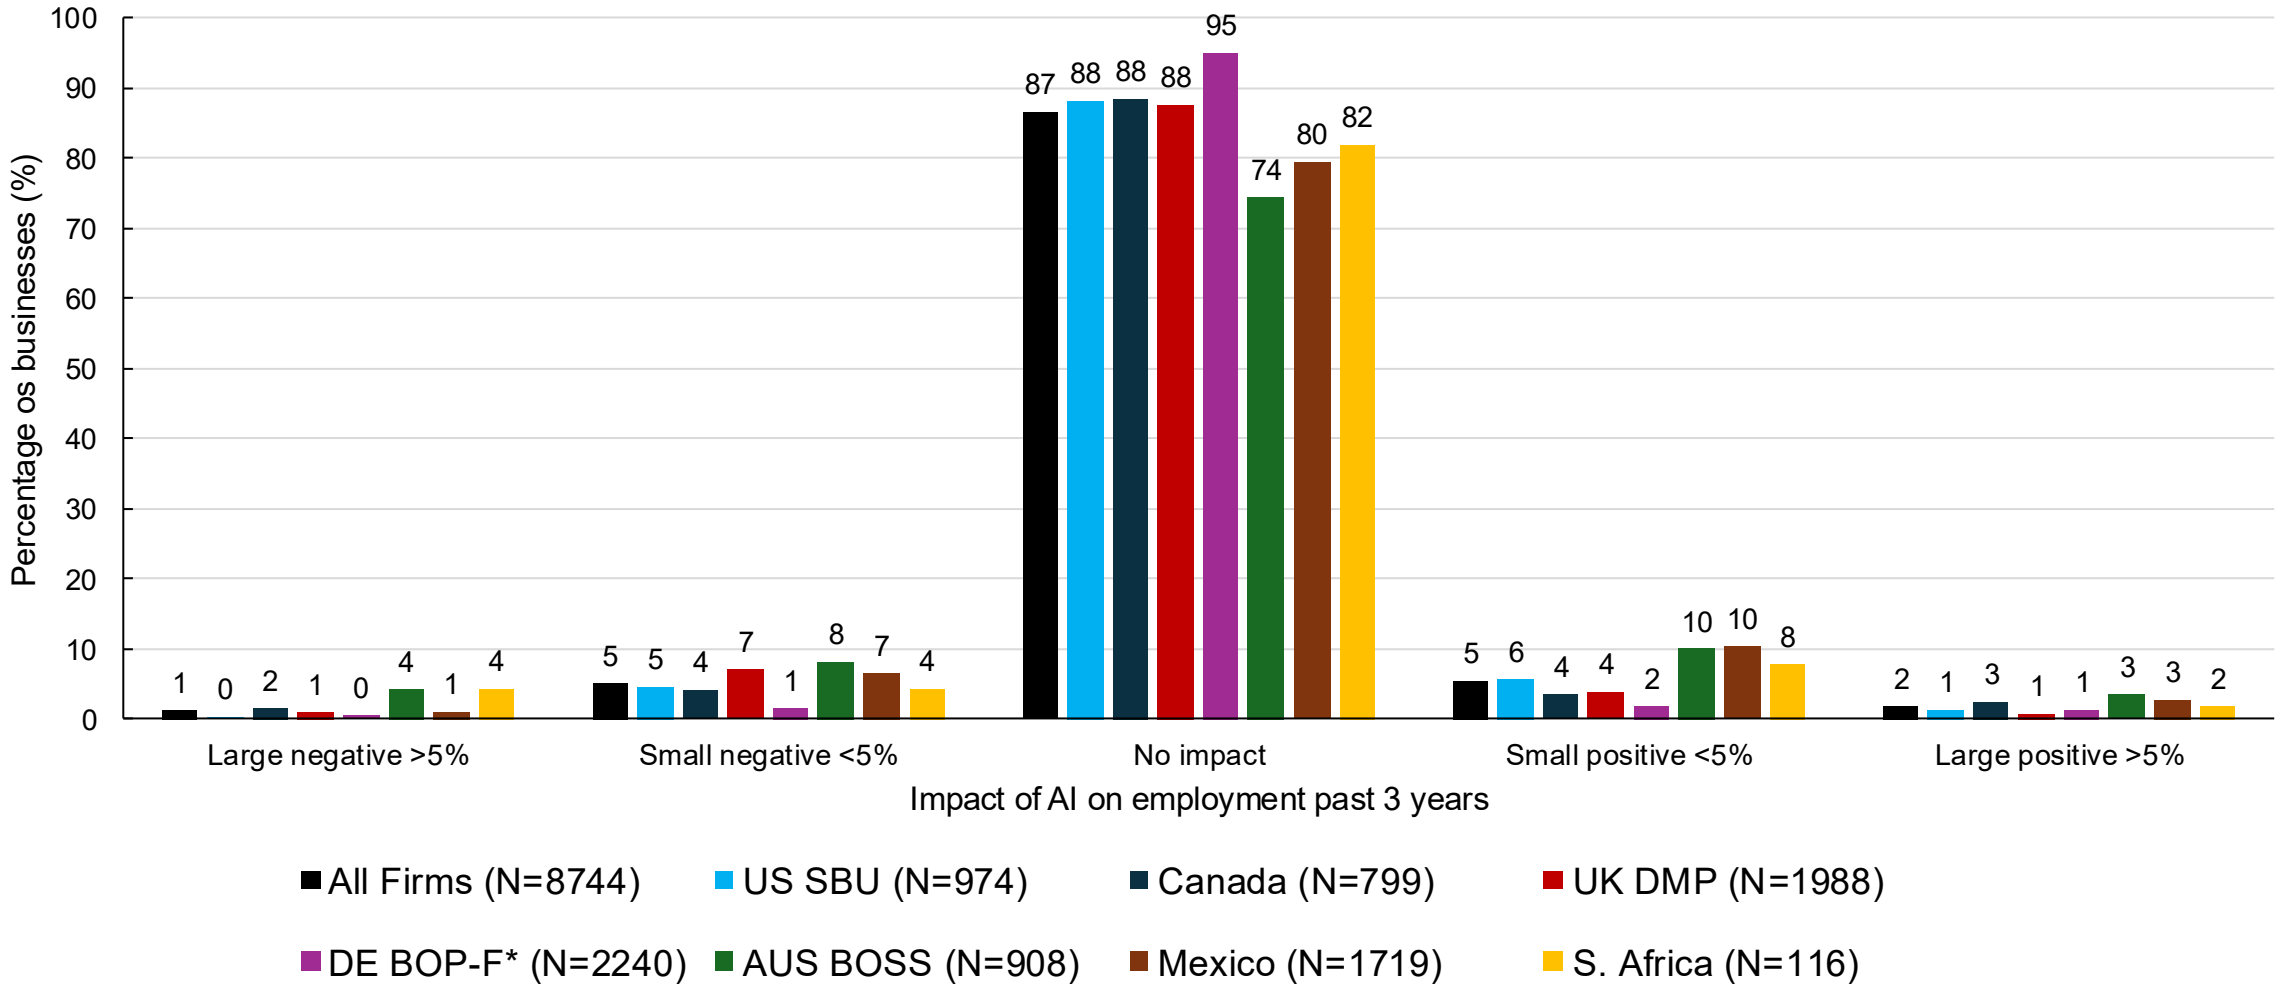

***Notes**: This figure is based on responses to the question: "On average, how frequently do you personally use artificial intelligence technologies in a typical working week?" The data for all seven countries was collected over May to July 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 8A Impact of AI on employment over past 3 years

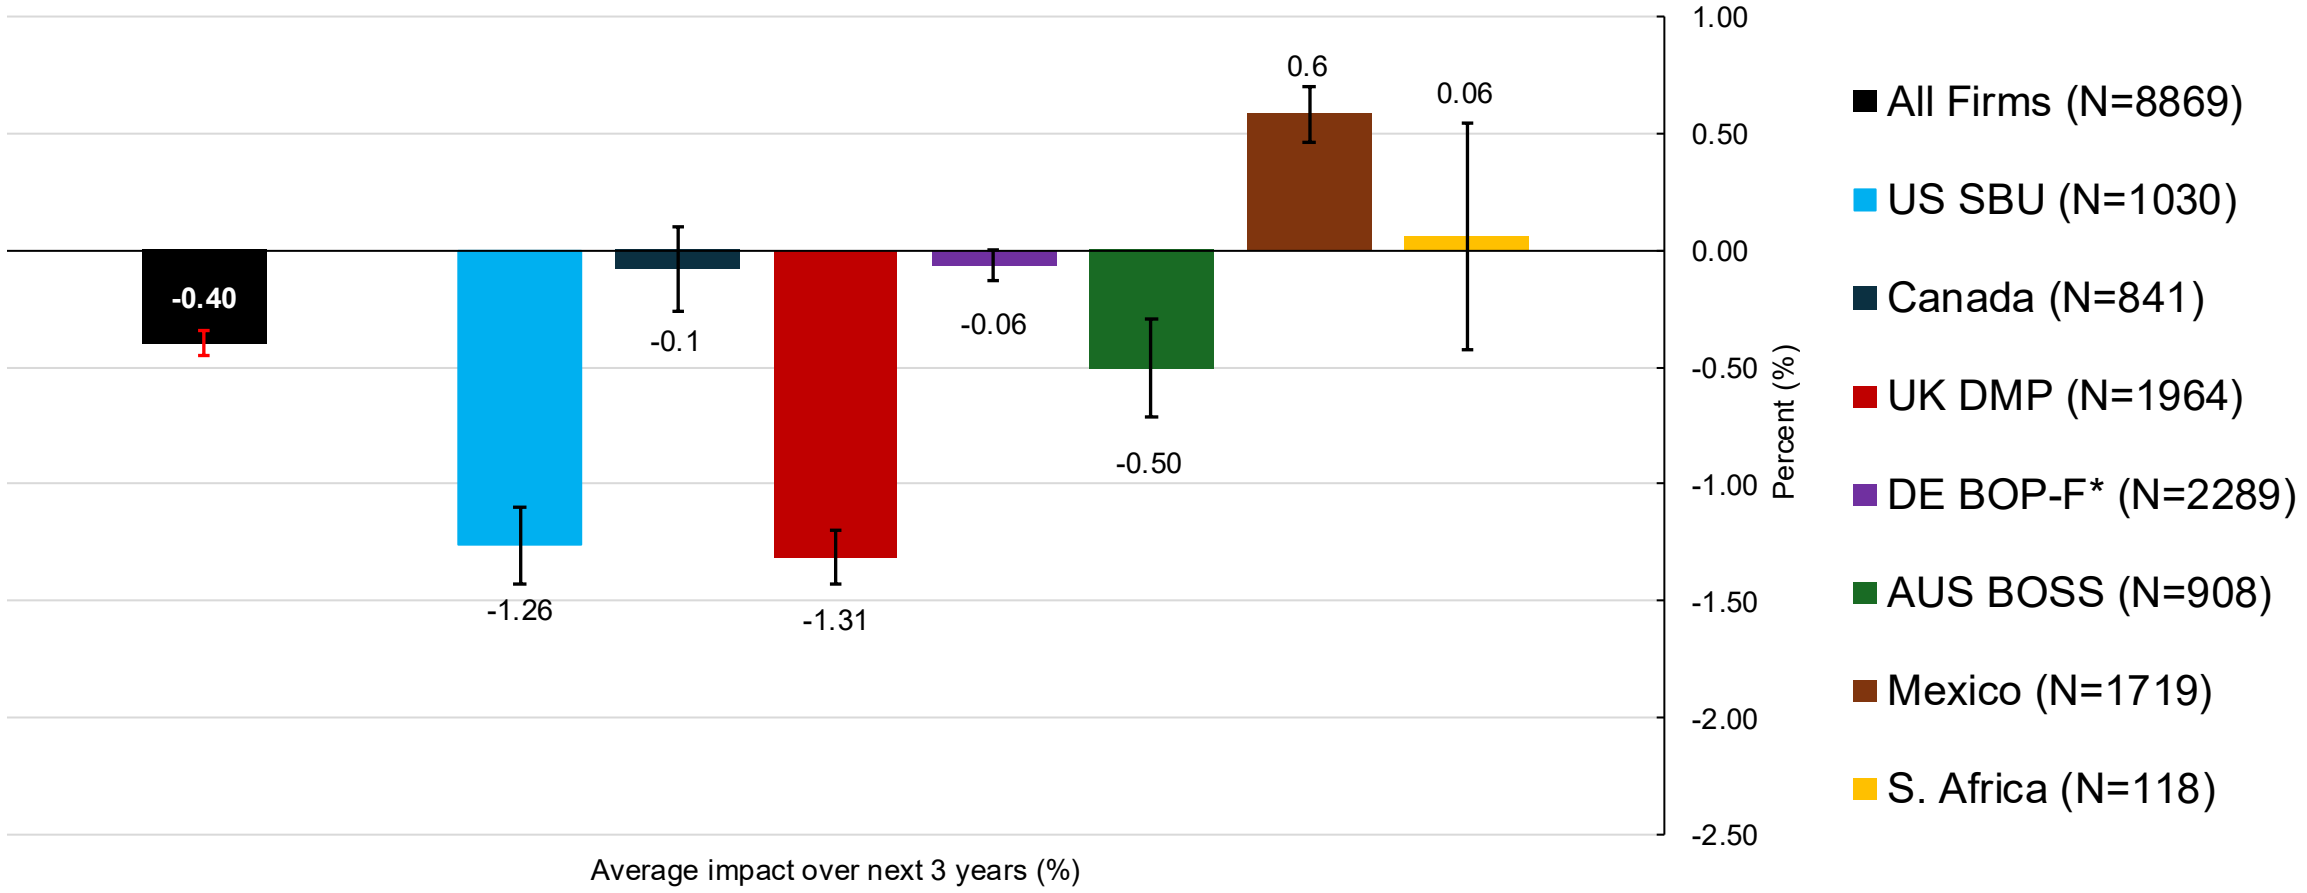

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected the number of employees in your business over the past three years?" To calculate the average impacts, values are assigned to each of the options: large negative/large positive impacts are treated as $\pm 7.5\%$; small negative/small positive impacts are treated as $\pm 2.5\%$. 90% confidence intervals are shown for these impacts. The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 8B Impact of AI on employment over past 3 years

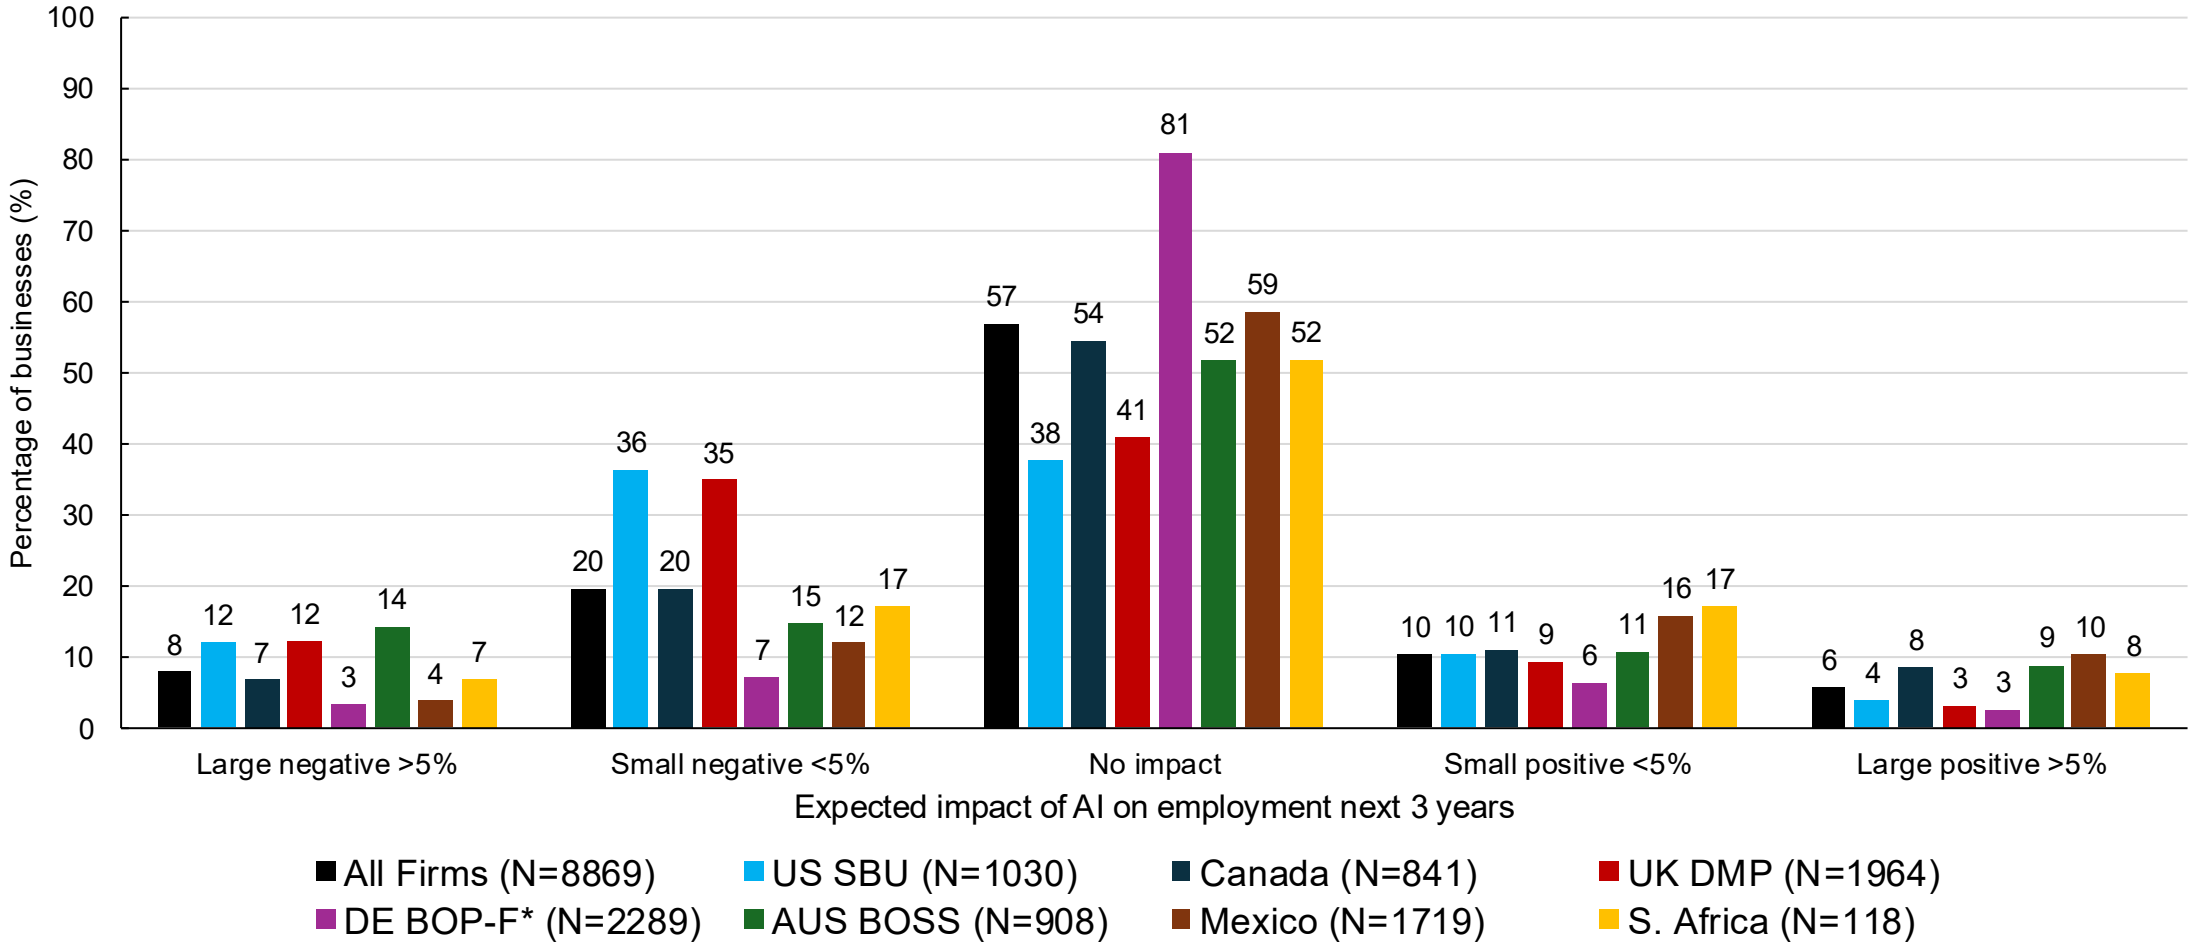

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected the number of employees in your business over the past three years?" The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 9A Expected impact of AI on employment over next 3 years

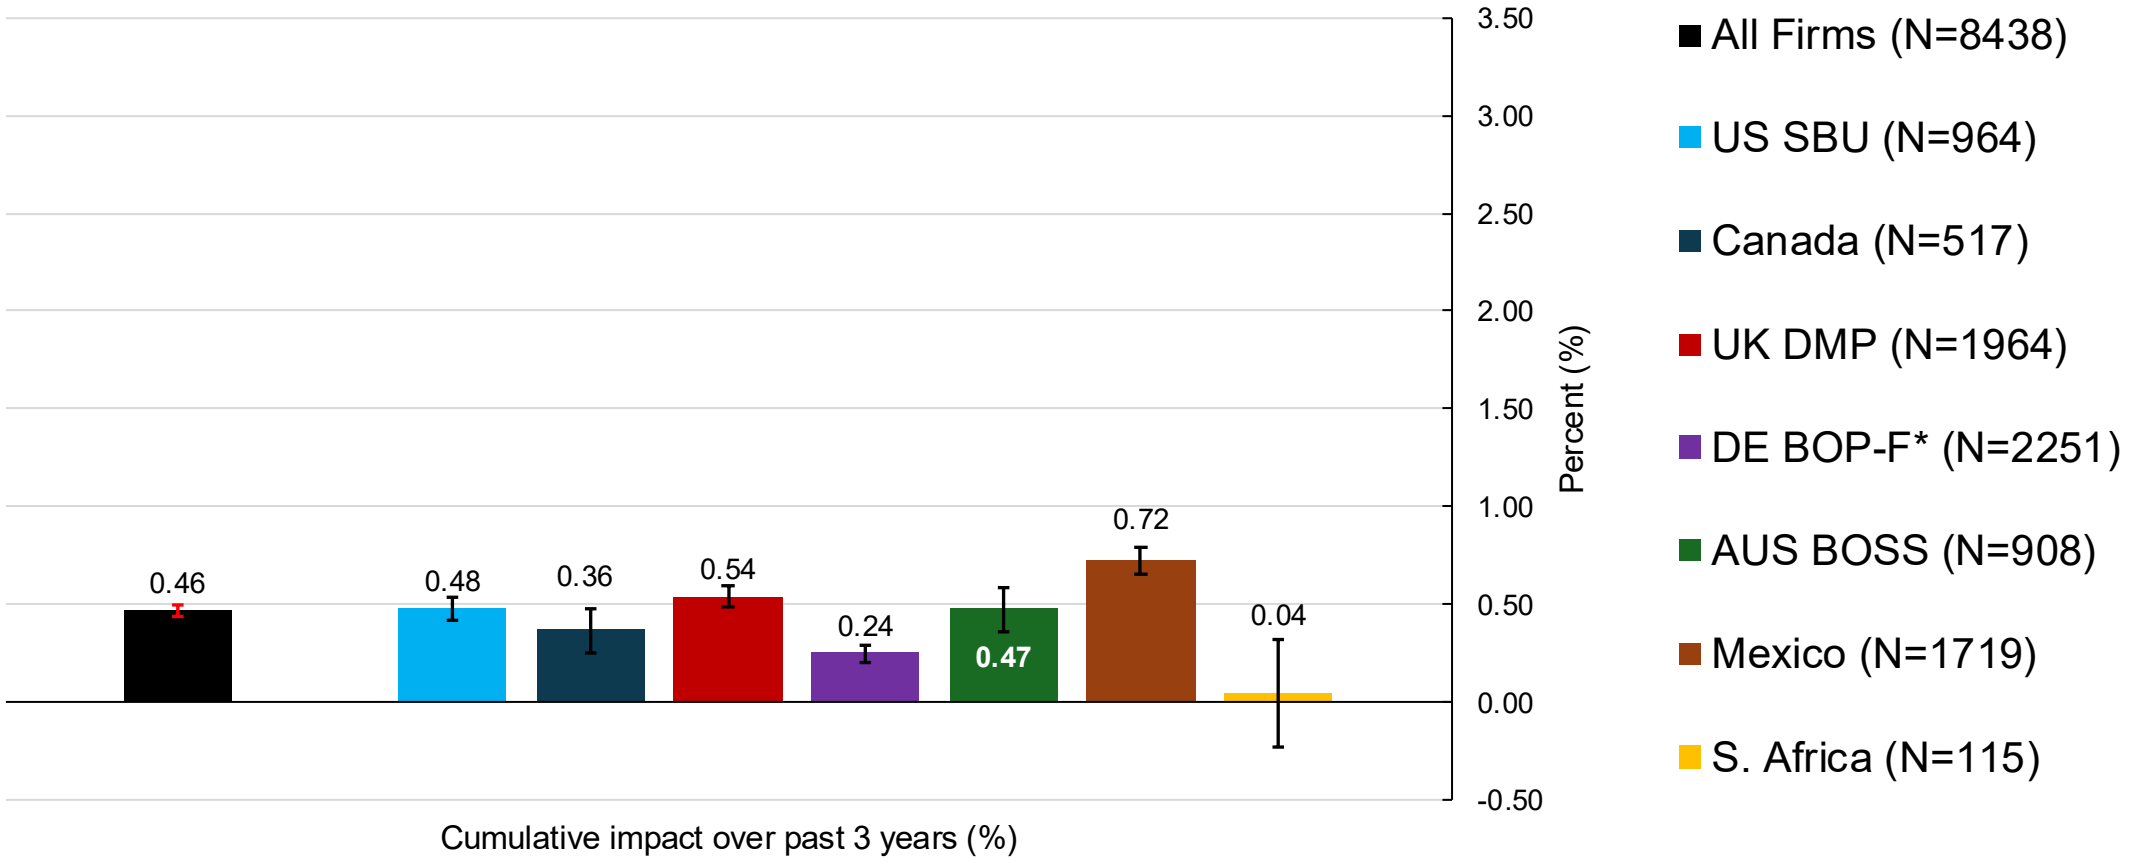

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected the number of employees in your business over the past three years? And how do you expect this to affect your number of employees over the next 3 years?" To calculate the average impacts, values are assigned to each of the options: large negative/large positive impacts are treated as $\pm 7.5\%$; small negative/small positive impacts are treated as $\pm 2.5\%$. 90% confidence intervals are shown for these impacts. The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 9B Expected impact of AI on employment over next 3 years

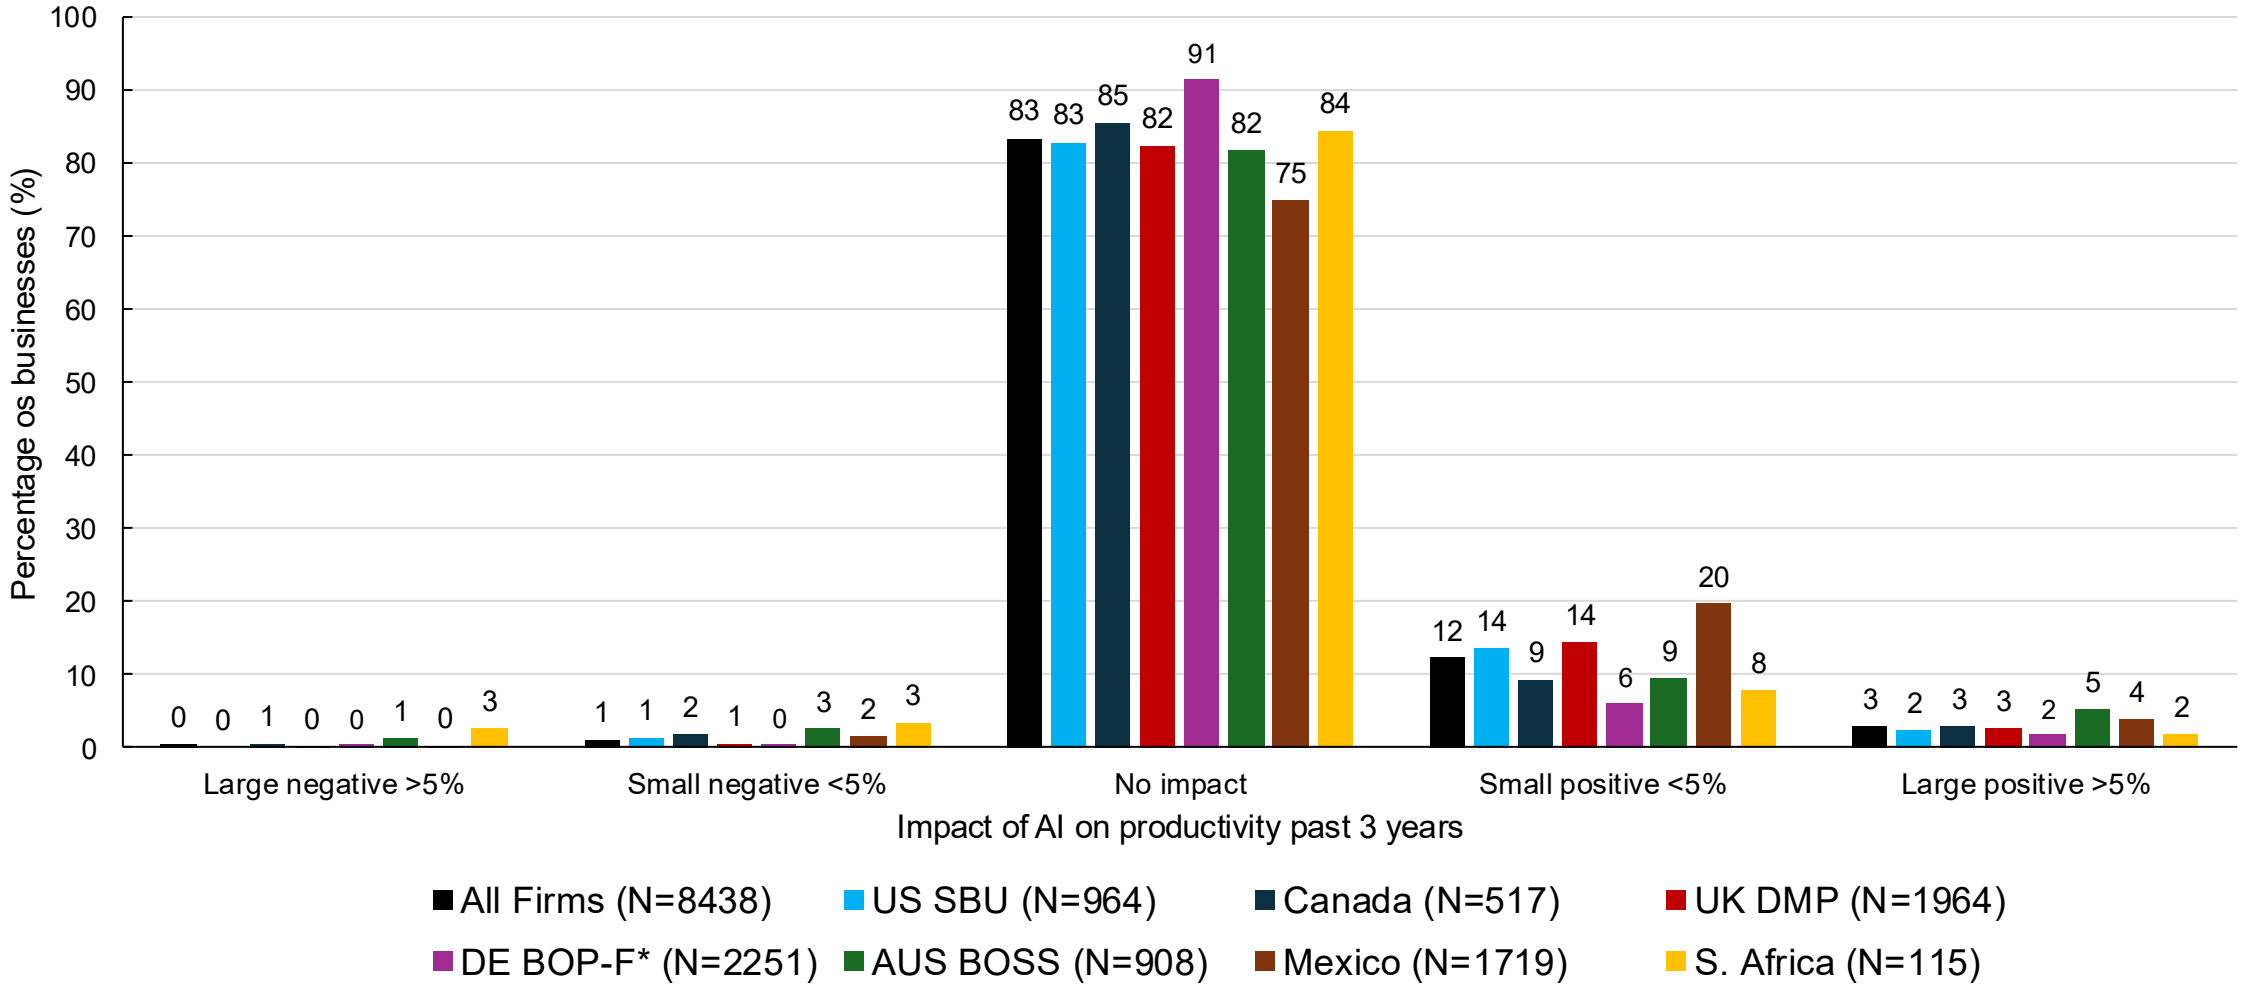

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected the number of employees in your business over the past three years? And how do you expect this to affect your number of employees over the next 3 years?" The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 10A Impact of AI on productivity over past 3 years

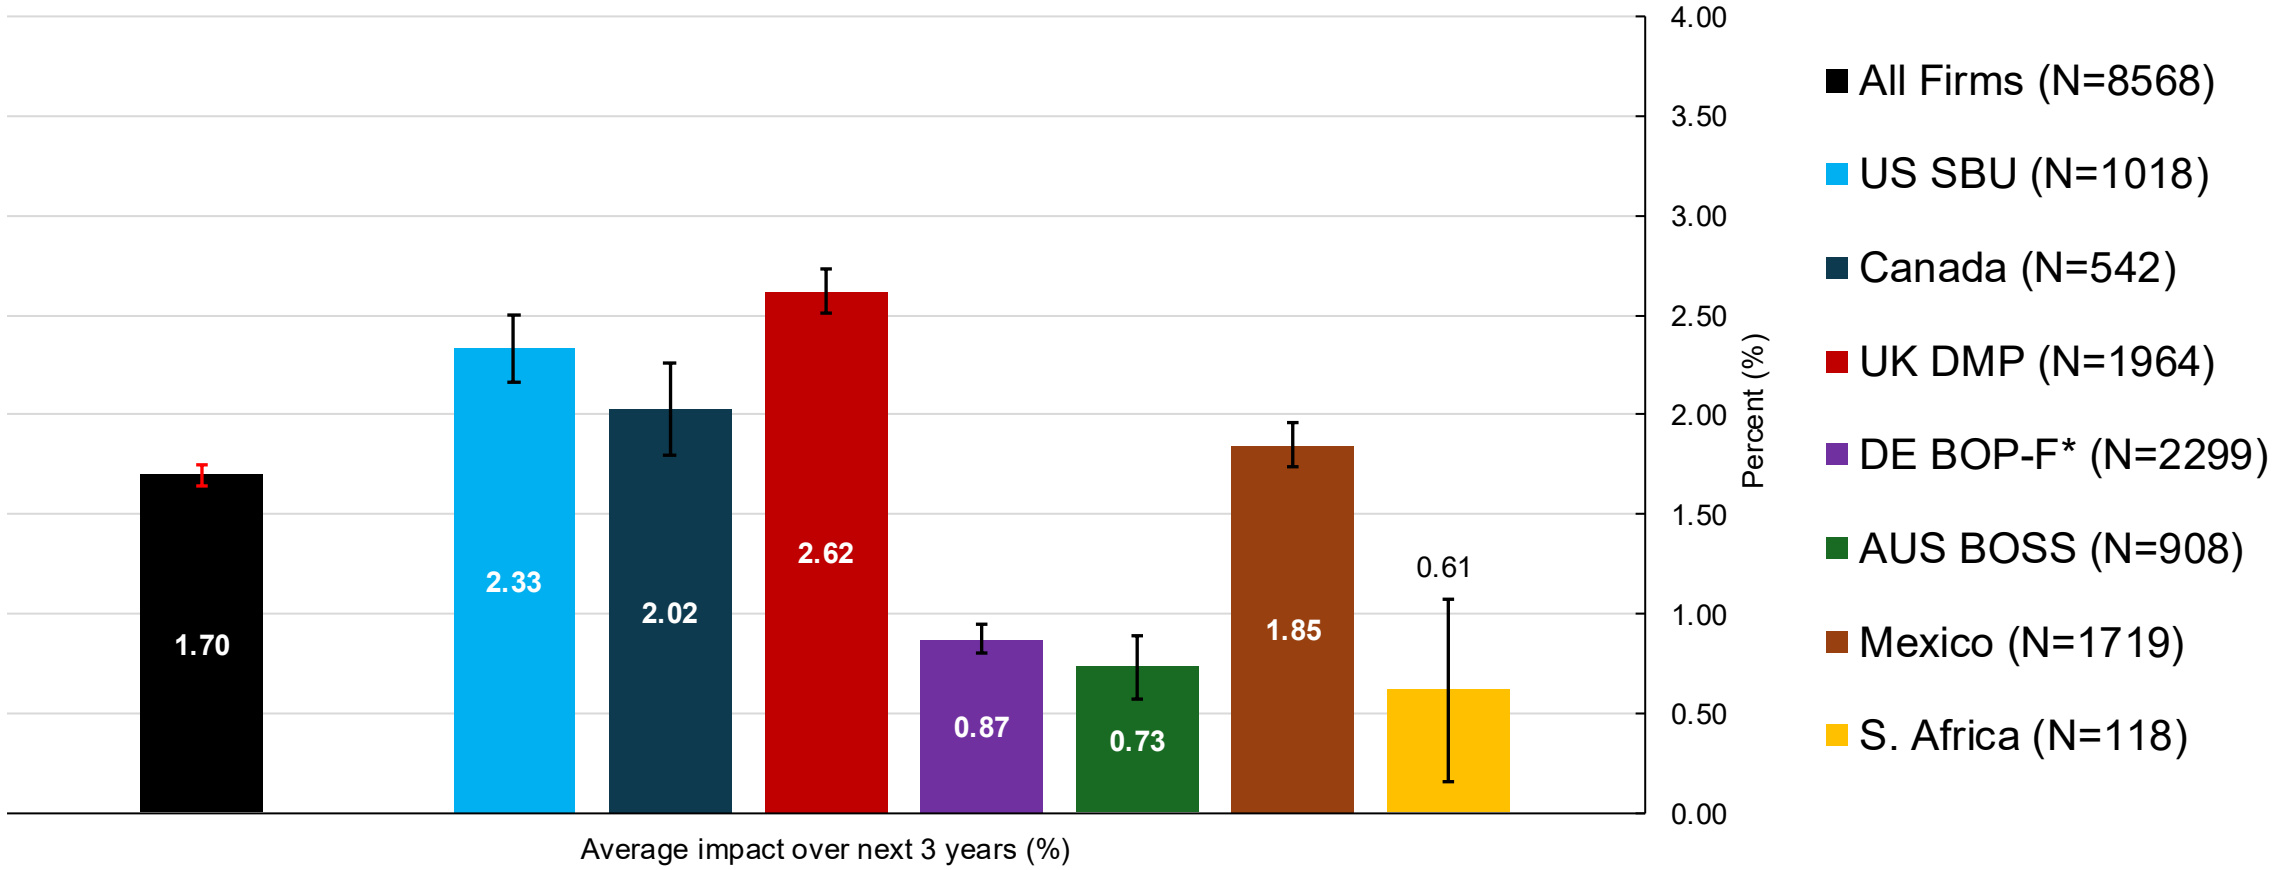

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected the volume of sales per employee in your business over the past three years?" To calculate the average impacts, values are assigned to each of the options: large negative/large positive impacts are treated as $\pm$ 7.5%; small negative/small positive impacts are treated as $\pm$2.5%. 90% confidence intervals are shown for these impacts. The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 10B Impact of AI on productivity over past 3 years

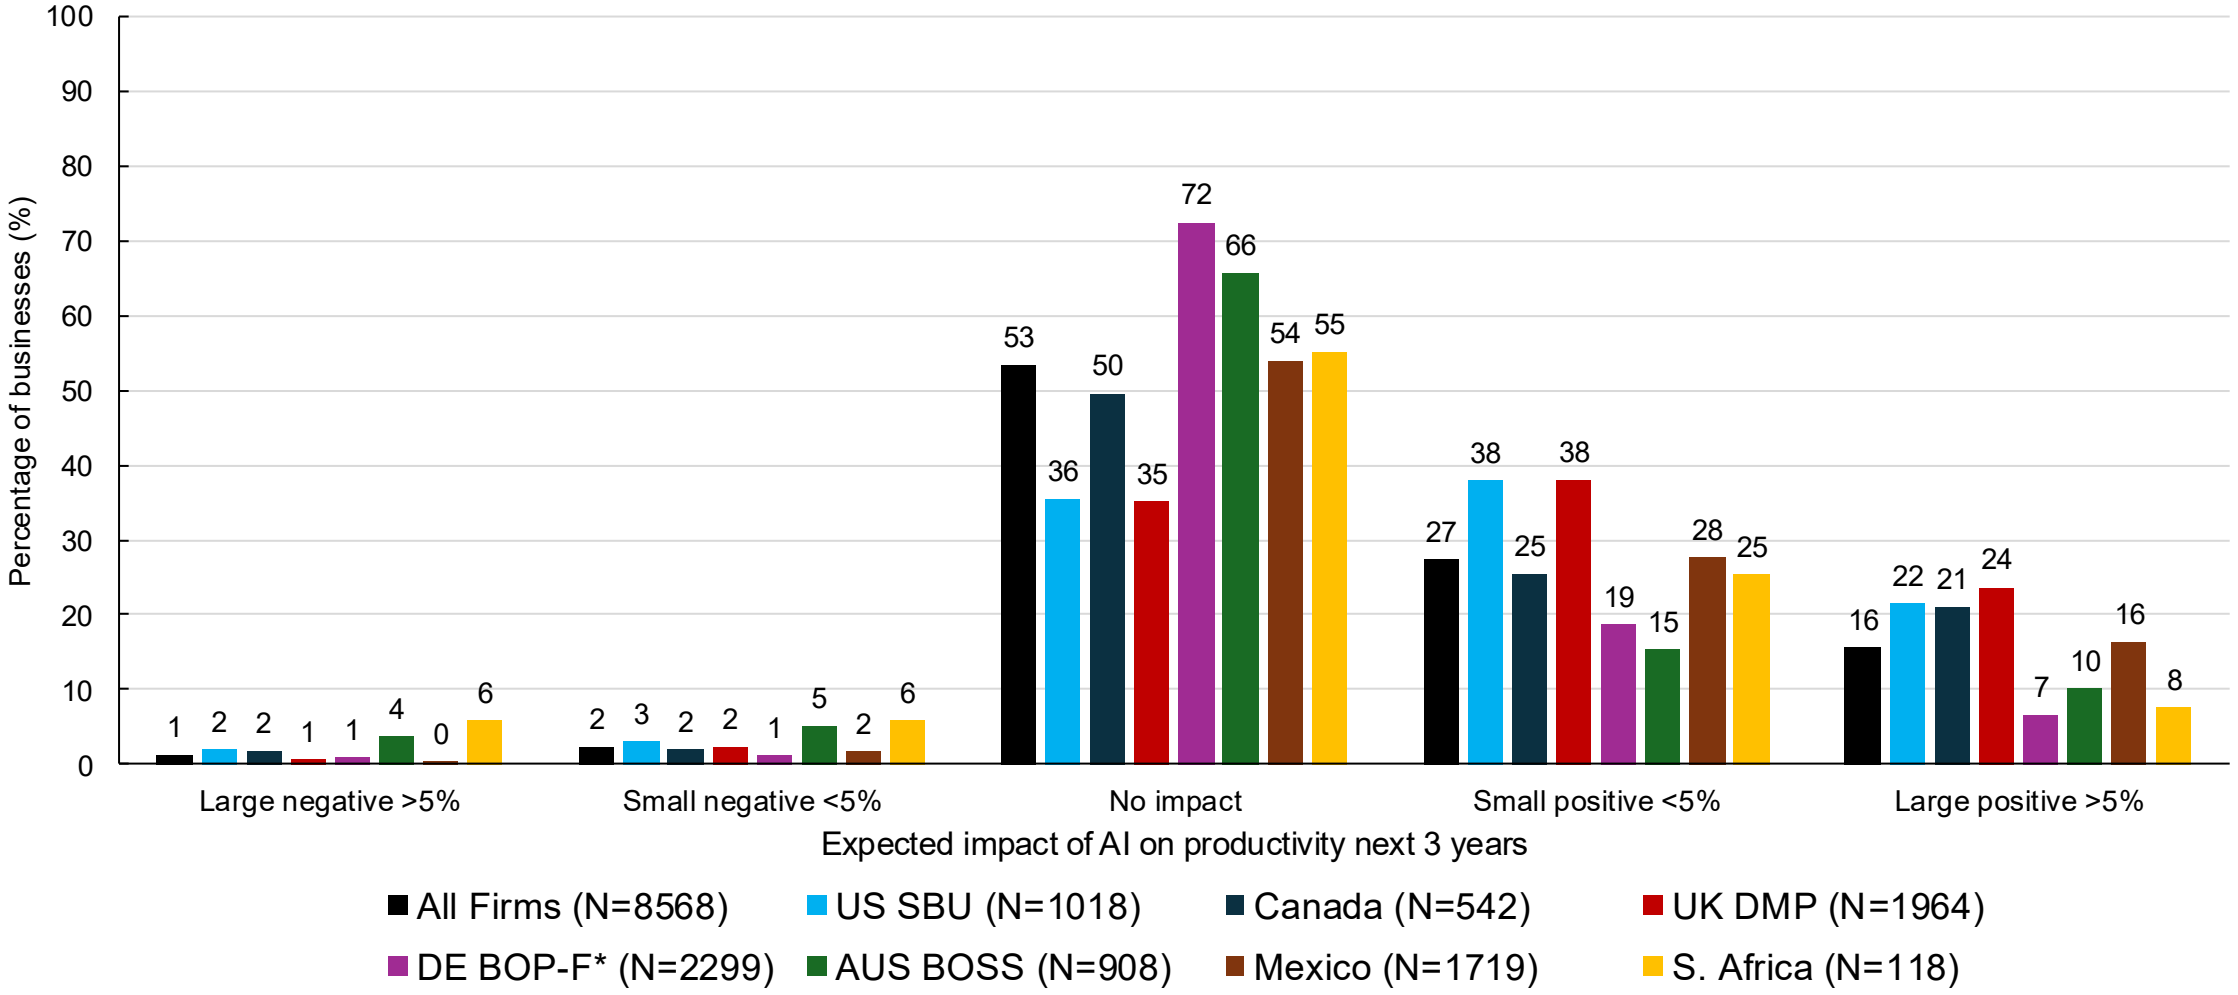

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected the volume of sales per employee in your business over the past three years?" The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 11A Expected impact of AI on productivity over next 3 years

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected volume of sales per employee in your business over the past three years? And how do you expect this to affect your volume of sales per employee over the next 3 years?" To calculate the average impacts, values are assigned to each of the options in Panel A: large negative/large positive impacts are treated as ±7.5%; small negative/small positive impacts are treated as ± 2.5%. 90% confidence intervals are shown for these impacts. The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure 11B Expected impact of AI on productivity over next 3 years

***Notes**: This figure is based on responses to the question: "How has the adoption of artificial intelligence technologies affected volume of sales per employee in your business over the past three years? And how do you expect this to affect your volume of sales per employee over the next 3 years?" The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

***Notes**: The data in Columns 1-2 and 5-10 in the UK Decision Maker Panel was collected over February-April 2025, November 2025 – January 2026, and May-July 2026 with the latest firm observation used in the regressions. The data on AI spending in 2026 was collected over August-September 2026. A constant has also been estimated, but not reported in the table. Where data are missing for a particular variable a dummy variable is included to account for that (results not reported). Standard errors are clustered at the firm level, stars indicate *** p<0.01, ** p<0.05, * p<0.1.*

Table 2 Distribution of AI spending per employee

	US Firms (SBU)		UK Firms (DMP)	
	2025	**2026**	**2025**	**2026**
10th percentile	$0	$0	$0	$0
25th percentile	$11	$41	$0	$26
50th percentile	$125	$294	$41	$136
75th percentile	$746	$1,366	$223	$450
90th percentile	$2,400	$5,000	$649	$1,380
Mean	$1,363	$2,043	$422	$725
Top 10% of Firms	$5,129	$7,480	$3,408	$5,197

***Notes**: This table shows the distribution of AI spending per employee (employment weighted) using data collected from the US and UK. Respondents were asked to answer the following two question: (1) Thinking back to last year (calendar year 2025), approximately how much did your firm spend on artificial intelligence adoption and AI related technologies? Include software, subscription services, hardware, worker training and IT staff support. (2) Now think about this year. For calendar year 2026, approximately how much do you expect your firm will spend on artificial intelligence adoption and AI related technologies? Include software, subscription services, hardware, worker training and IT staff support. Columns 1-2 based on 845 responses from firms in the US Survey of Business Uncertainty in March 2026. Columns 3-4 are based on 1,273 responses to the Decision Maker Panel in August-September 2026. Original responses in Columns 3-4 are in GBP and converted to USD using exchange rate of 1.35 $/£"*

Table 3 Expected AI contributions to productivity over next 3 years: Splitting up into labour productivity and TFP impacts (UK)

Summary - Average impacts on annual growth (pp)

	Last 3 years	Next 3 years
Sales per employee	0.18	0.69
Labor productivity (GVA per employee)	0.17	0.85
Total Factor Productivity (TFP)	0.13	0.68

***Notes**: The calculations combine estimated effects of AI adoption on firms' sales per employee, employment with aggregate UK national accounts data and data on AI-related expenditures. Aggregate output is calculated as employment multiplied by sales per employee, while gross value added (GVA) equals output less intermediate consumption. AI spending data is based on data collected from the DMP over August-September 2026 and is assumed to increase intermediate consumption in proportion to employment (£313 and £537 per worker per year in the past 3 years and next 3 years, respectively). Labour productivity is measured as GVA per worker. The contribution to total factor productivity (TFP) is derived using a standard growth-accounting framework, calculated as the change in GVA less the weighted contributions of labour and capital inputs, with labour and capital shares of 0.67 and 0.33, respectively. Capital deepening is assumed to reflect AI-related expenditure equivalent to 6% of the aggregate capital stock. Reported figures are expressed as average annual contributions to growth over a three-year horizon.*

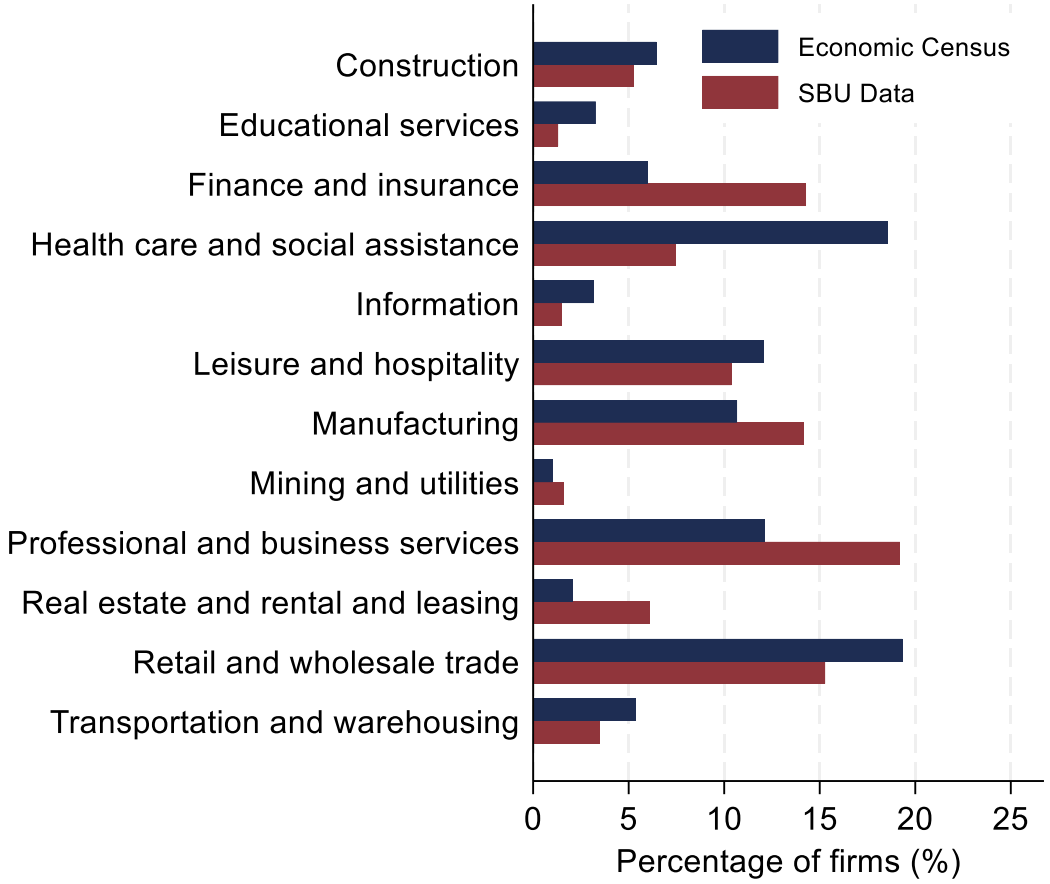

Table 4 Summary of realised and expected AI contributions

	Firms							
	All	**US (SBU)**	**Canada**	**UK (DMP)**	**Germany (BOP-F)***	**Australia (BOSS)**	**Mexico**	**South Africa**
Cumulative impact over past 3 years (%)								
Sales/Employee	0.46	0.48	0.36	0.54	0.24	0.47	0.72	0.04
Employment	0.06	0.10	0.06	-0.09	0.07	-0.01	0.22	-0.11
Output (implied)	0.52	0.58	0.42	0.44	0.32	0.46	0.95	-0.06
Expected cumulative impact over next 3 years (%)								
Sales/Employee	1.70	2.33	2.02	2.62	0.87	0.73	1.85	0.61
Employment	-0.40	-1.26	-0.08	-1.31	-0.06	-0.50	0.585	0.06
Output (implied)	1.30	1.07	1.94	1.31	0.81	0.23	2.43	0.68

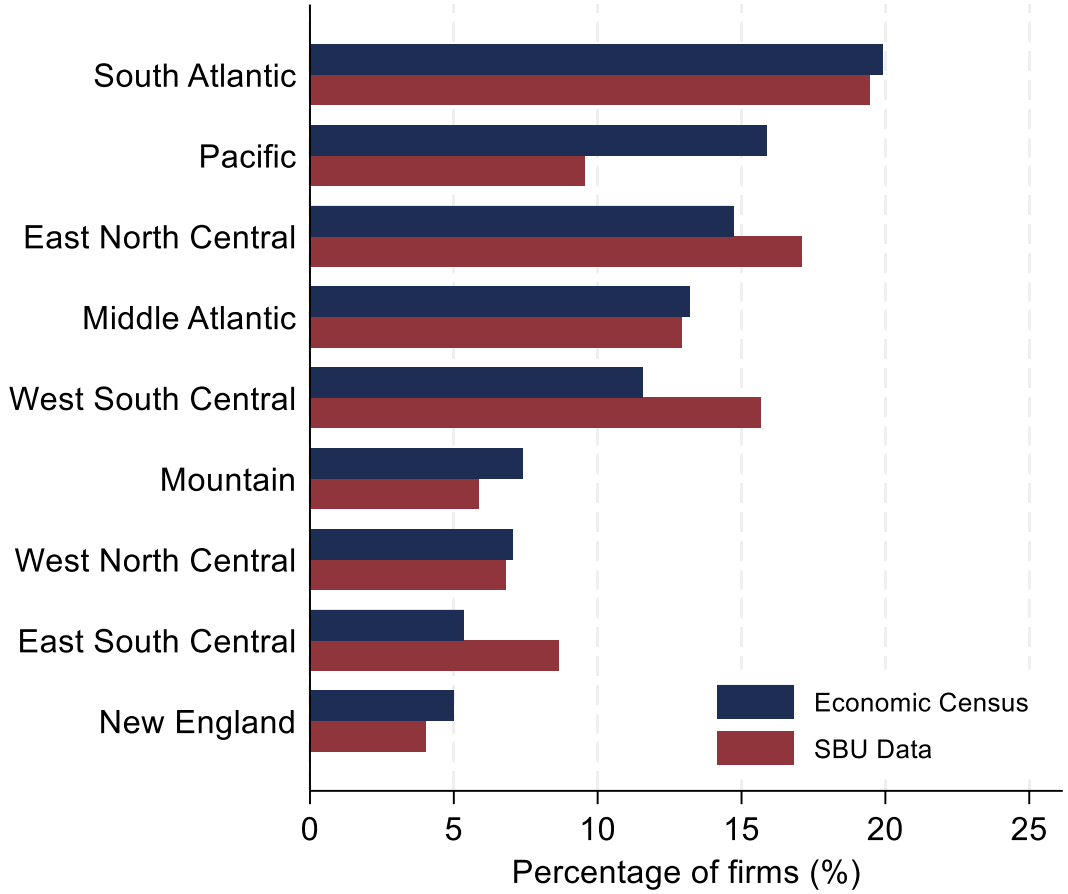

***Notes**: This table summarises the realised and expected AI impacts on sales per employee and employment from Figures 8-11. The implied impacts on output are calculated as the sum of the sales/employee and employment impacts. The data for the US, Canada, the UK, Australia, Mexico, and South Africa were collected over May-July 2026. The data for Germany were collected in January 2026. The results for all firms is the average of the seven surveys, weighted by the respective number of responses. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure A1 SBU vs. US industrial and regional distribution

Panel A: By Industry

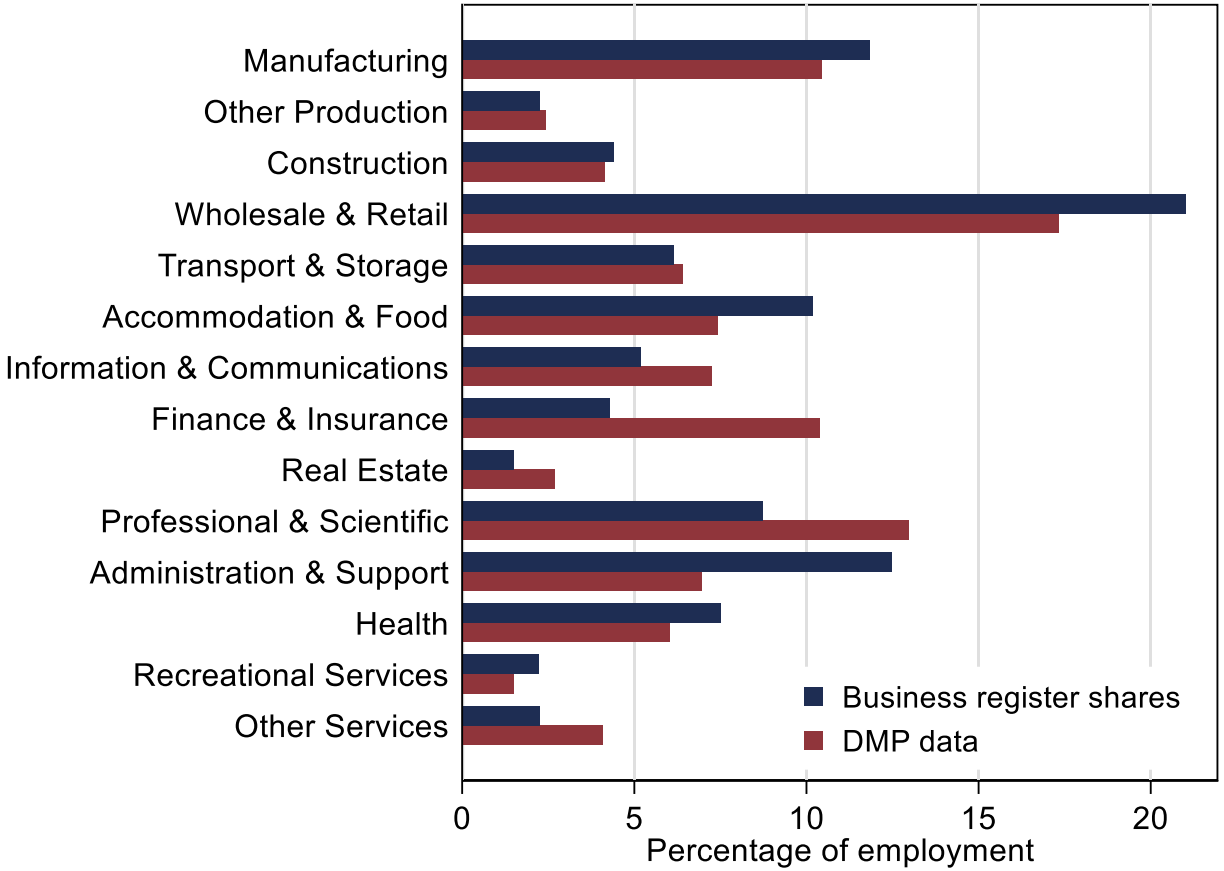

Panel B: By Region

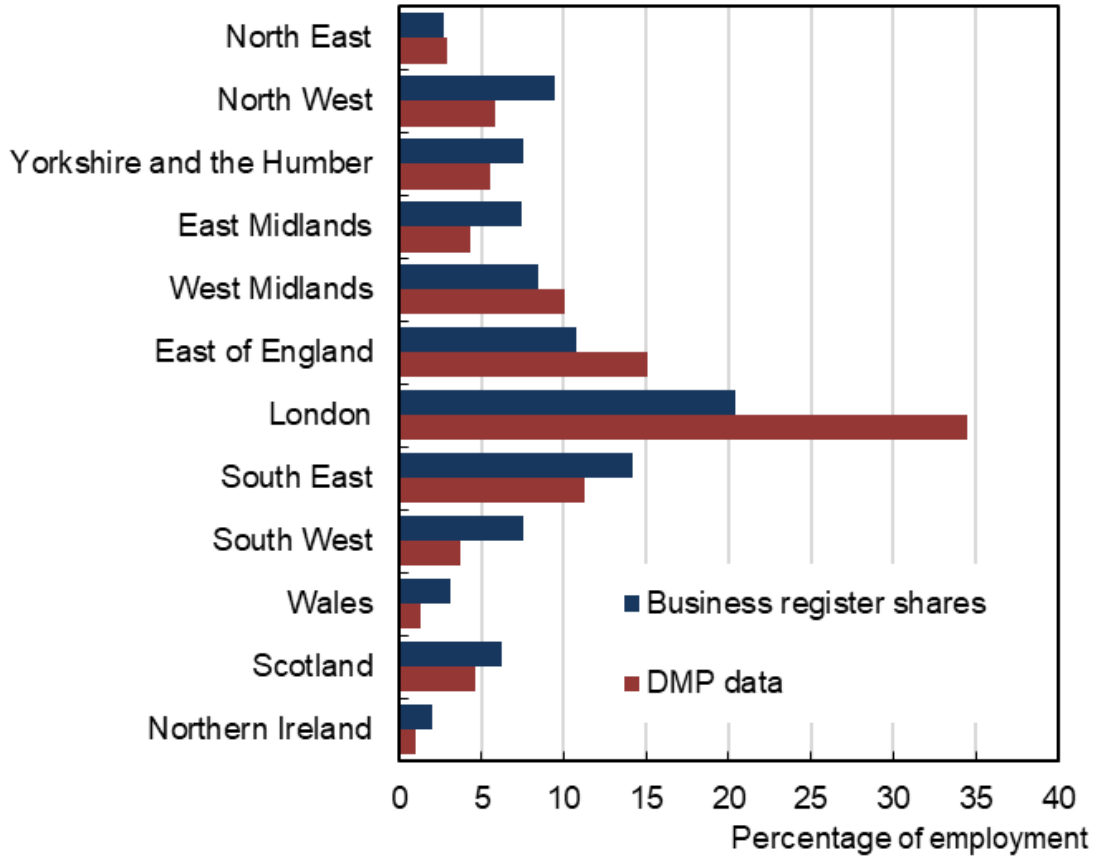

***Notes**: This figure compares the percentage of firms by industry (Panel A) and region (Panel B) in the US Survey of Business Uncertainty against the 2022 Economic Census. The shares are employment-weighted. Panel A is based on 6835 firms in the SBU. Panel B is based on 6995 firms in the SBU.*

Figure A2 DMP vs. UK industrial and regional distribution

Panel A: By Industry

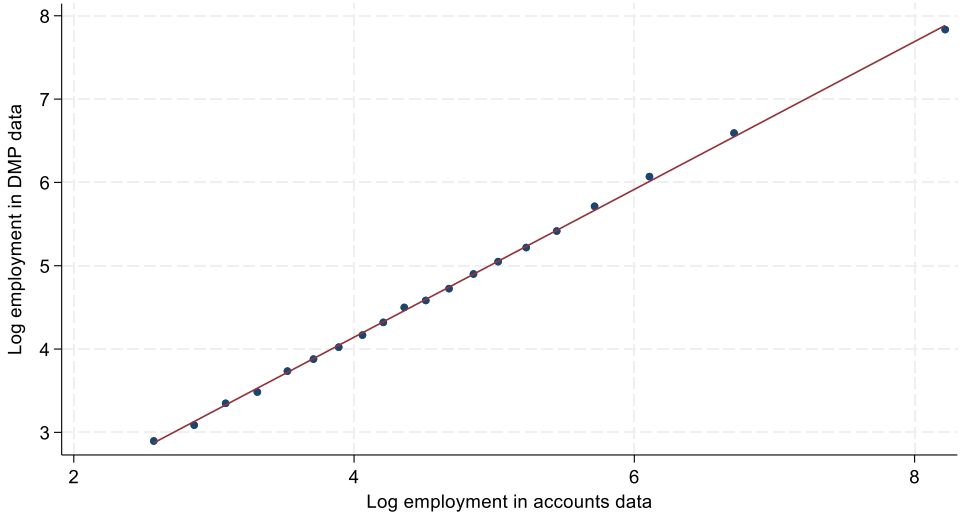

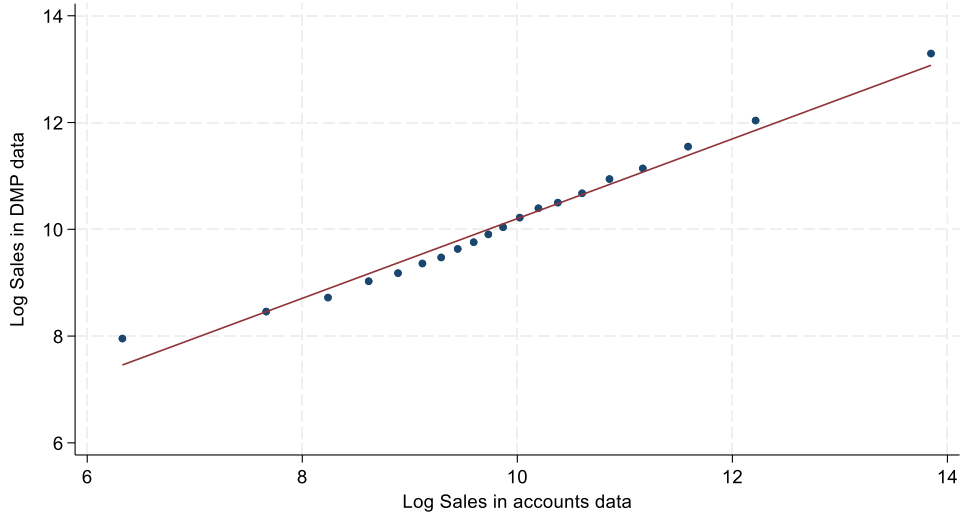

Panel B: By Region

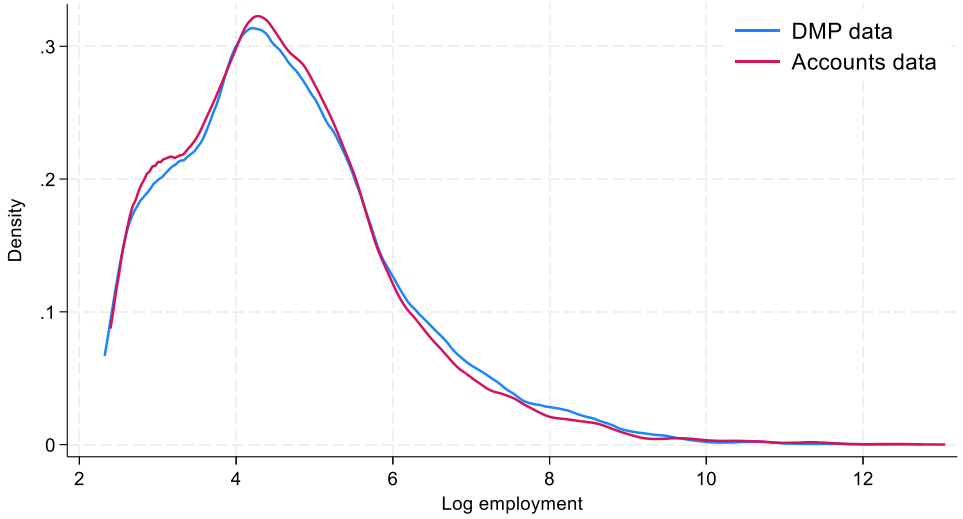

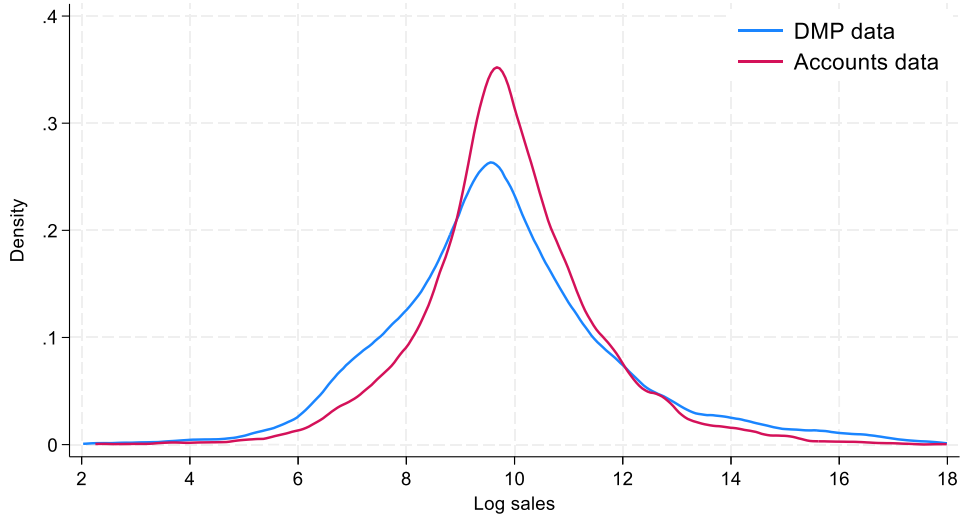

***Notes**: Other production includes agriculture; forestry & fishing; mining & quarrying; electricity, gas & air conditioning supply; water supply; and sewerage, waste management & remediation activities. Data are averages from 2017 to 2025.*

Figure A3 Firm responses vs. company accounts data (UK firms)

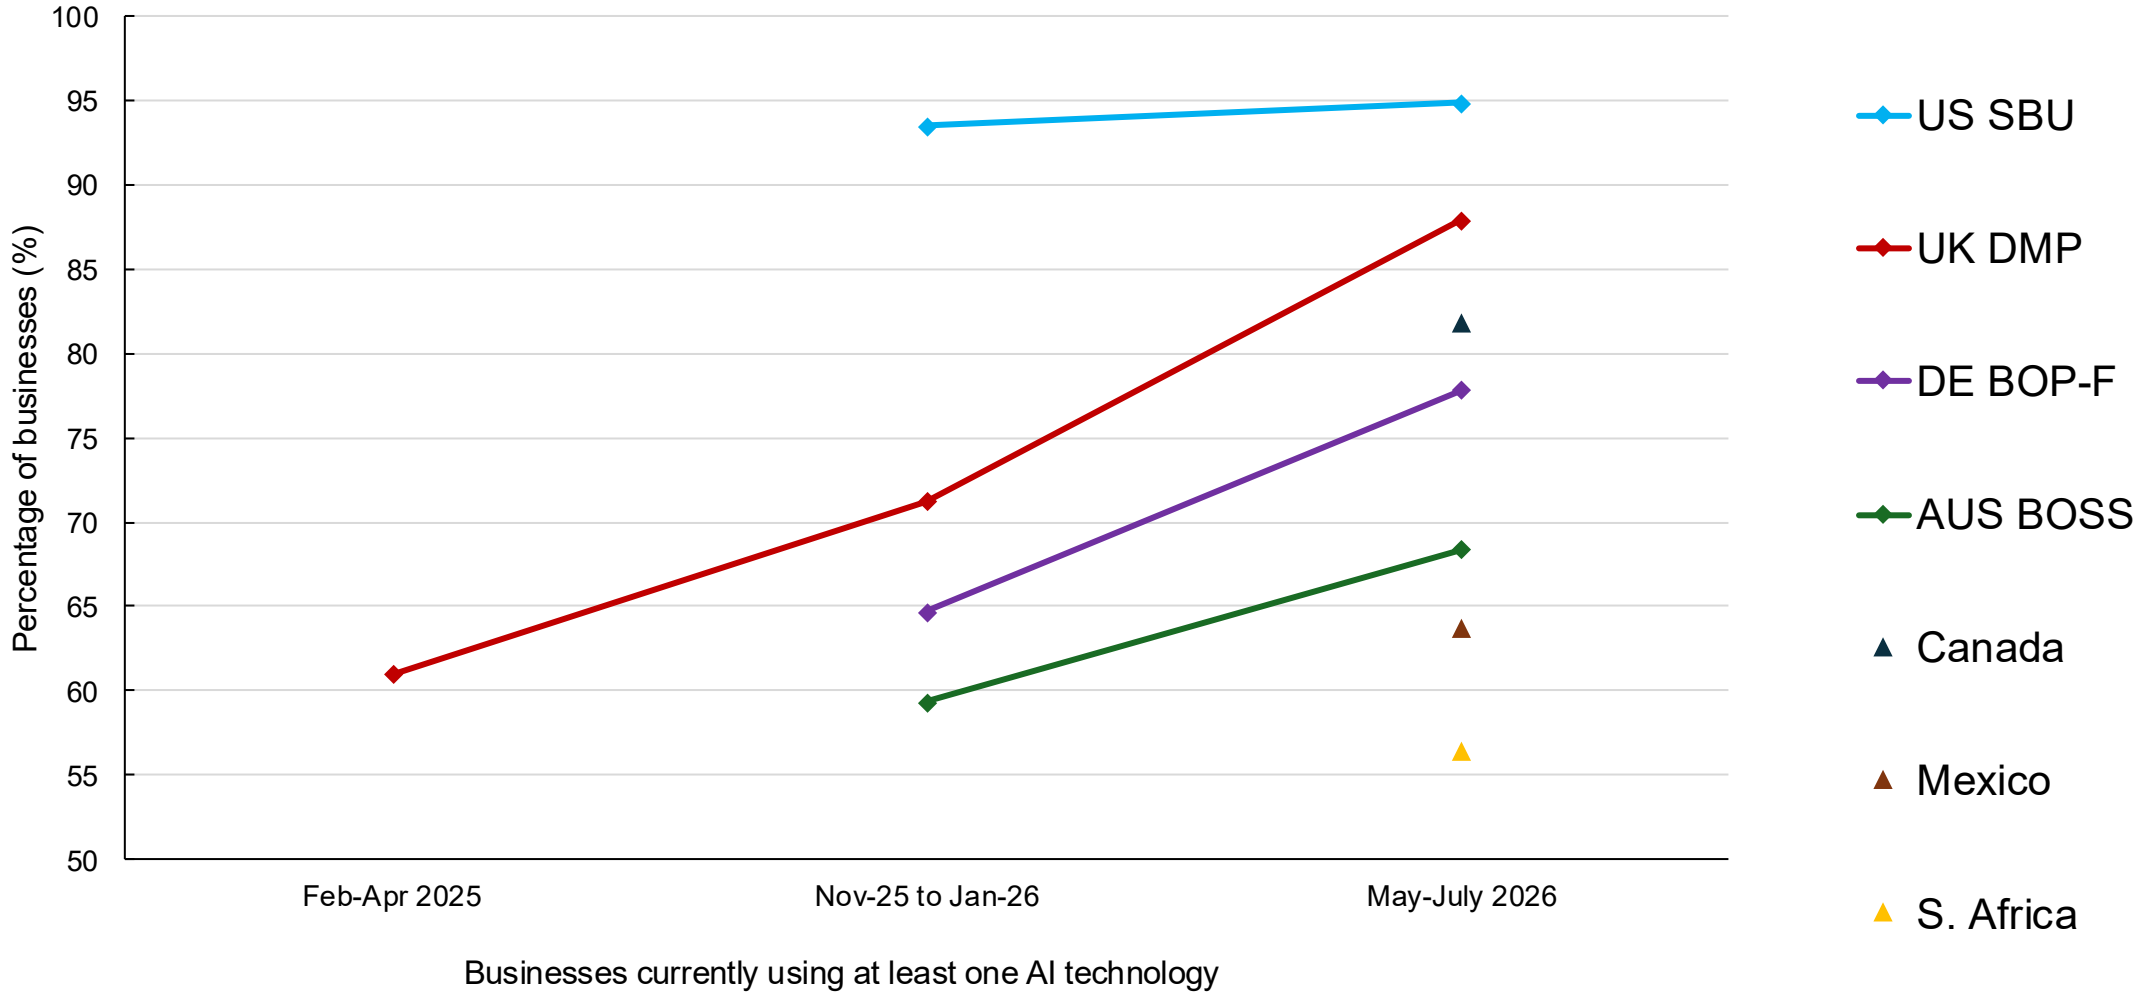

Notes: *Sales values from the DMP survey are annualised average quarterly sales reported by businesses across the year. DMP employment data are averages across the year. DMP data are plotted against annual company accounts data from Bureau Van Dijk for the corresponding financial year. The dots on the top charts each represent 5% of observations, grouped by log employment/sales from accounts data. Charts are based on annual data between 2017 and 2024.*

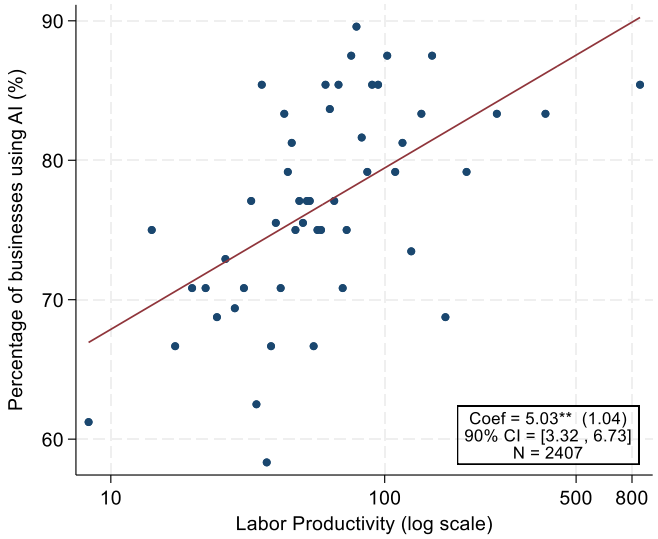

Figure A4 Current use of AI technologies by businesses

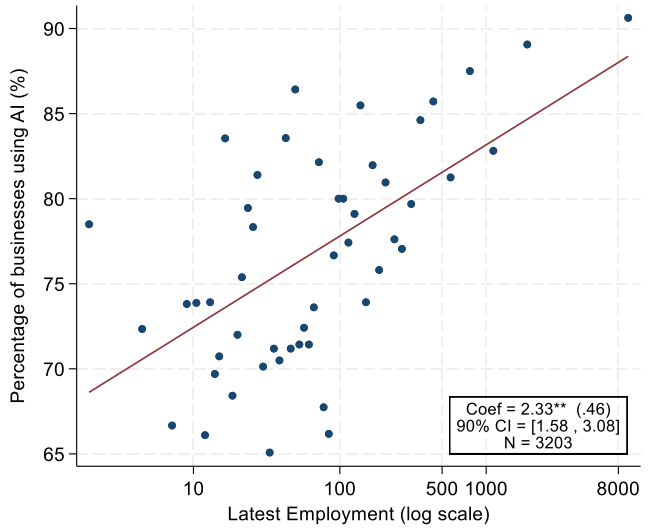

***Notes**: This figure is based on responses to the question: "Which of the following artificial intelligence technologies, if any, does your business currently use?" Firms could select more than one option. The results for the US, UK, Germany, and Mexico are employment-weighted. The results for Canada, Australia, and South Africa are equal-weighted.*

Figure A5.a Characteristics of firms using AI technologies (UK Firms)

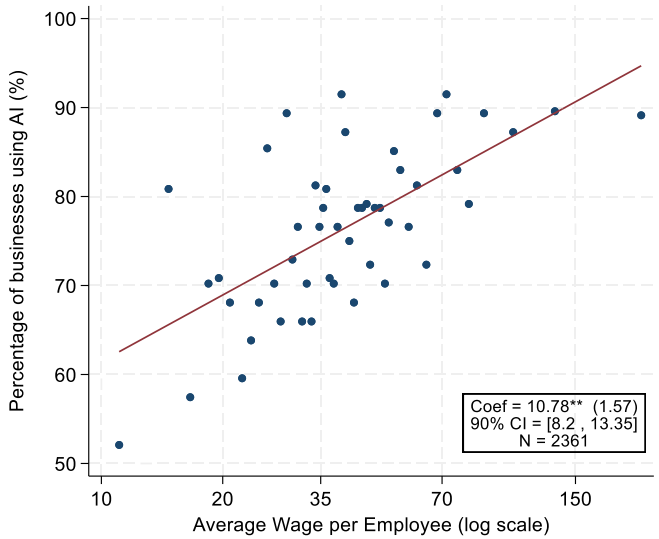

Panel A Labor Productivity

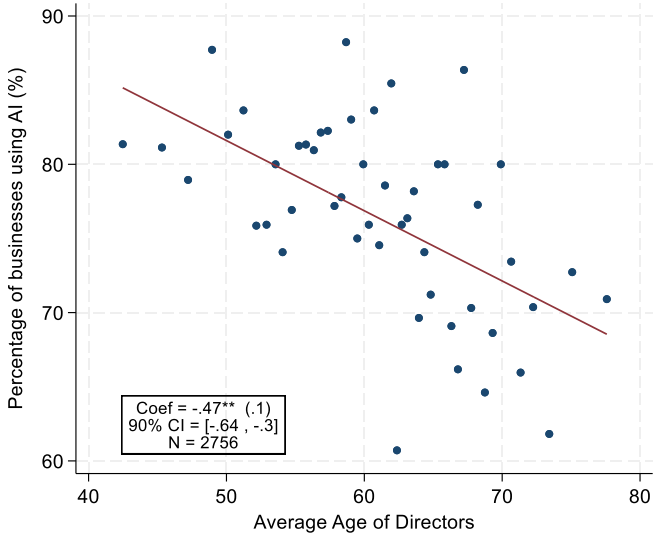

Panel B Firm employment

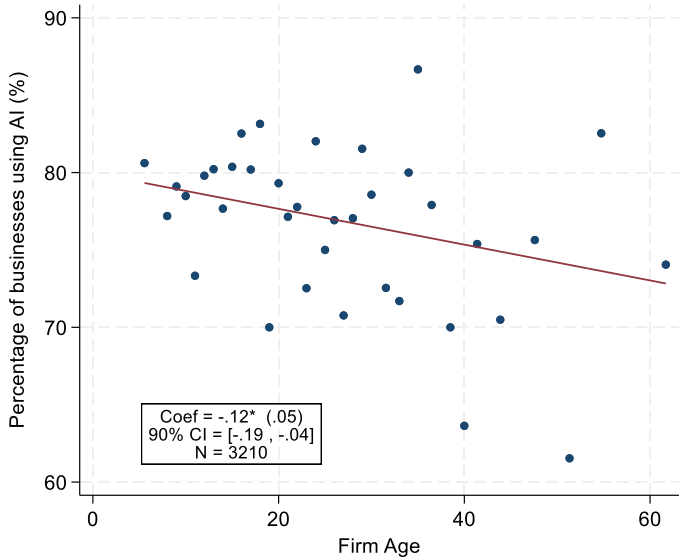

Panel C Average wage per employee

Panel D Average age of directors

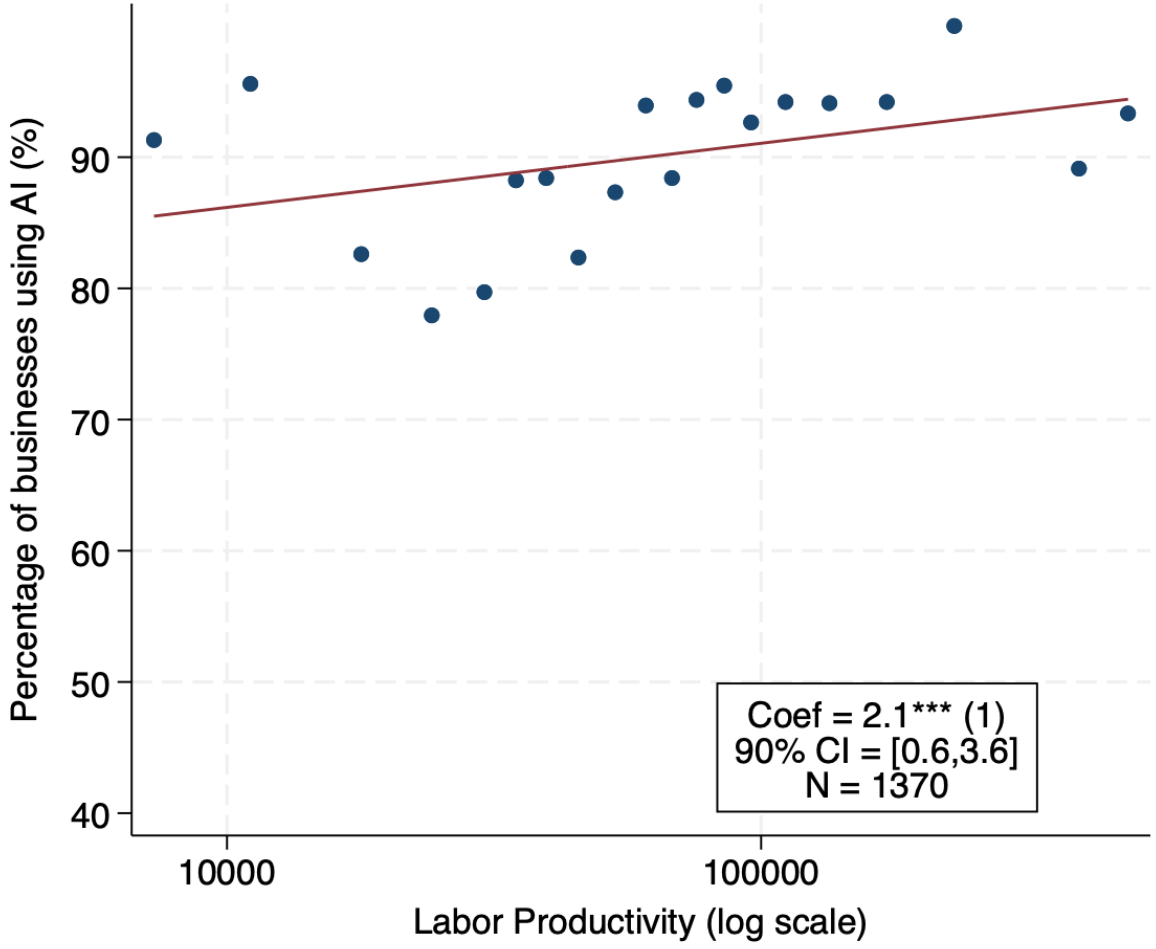

Panel E Firm age

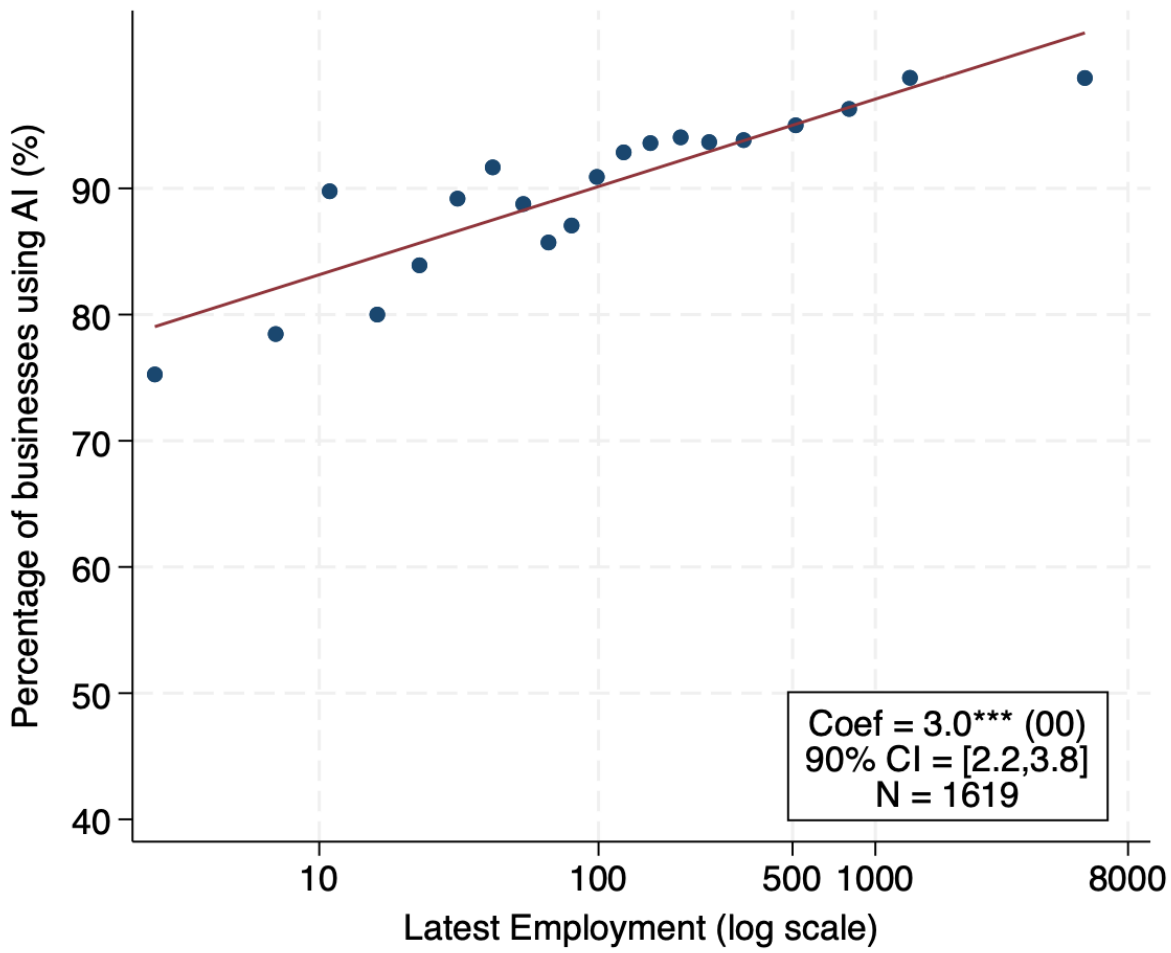

***Notes**: This figure shows binned scatter plots. The vertical axis is the percentage of businesses currently using any AI technology. The data are from the UK Decision Maker Panel, collected over February-April 2025, November 2025 – January 2026, and May-July 2026 with the latest firm observation used in the figures.*

Figure A5.b Characteristics of firms using AI technologies (US Firms)

Panel A Labor Productivity

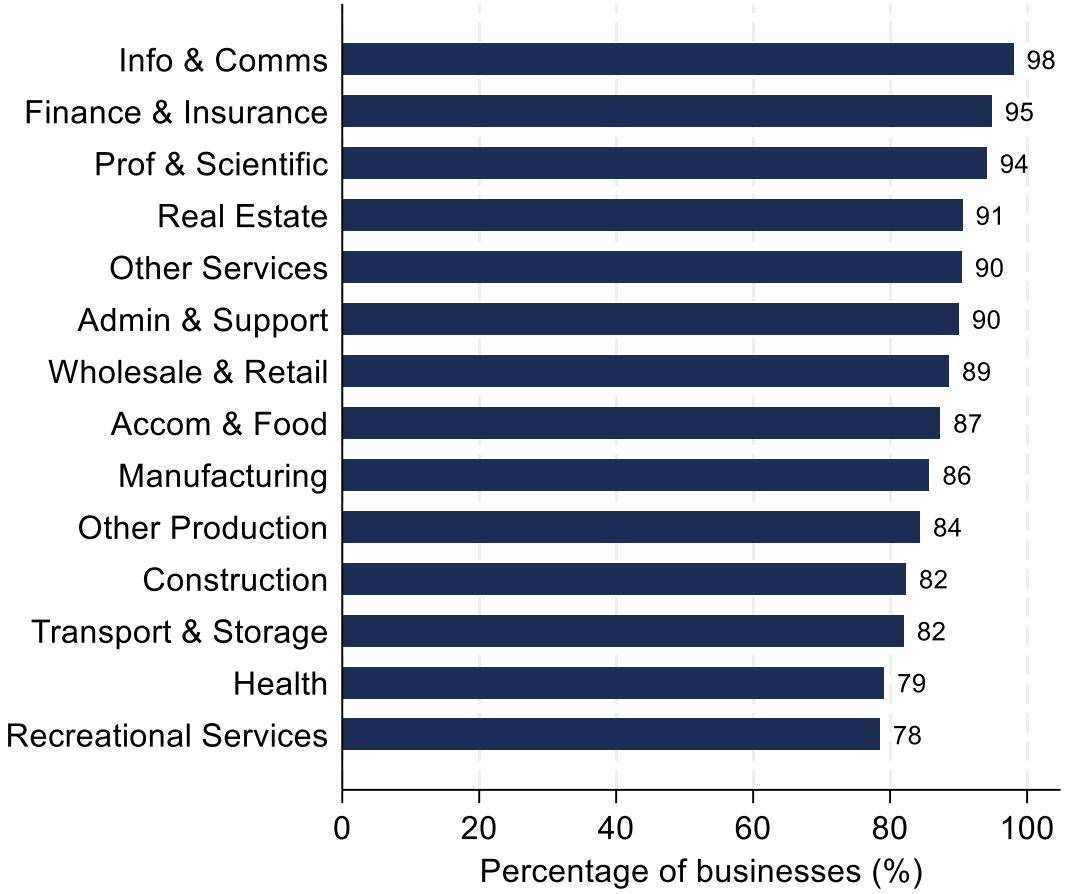

Panel B Firm employment

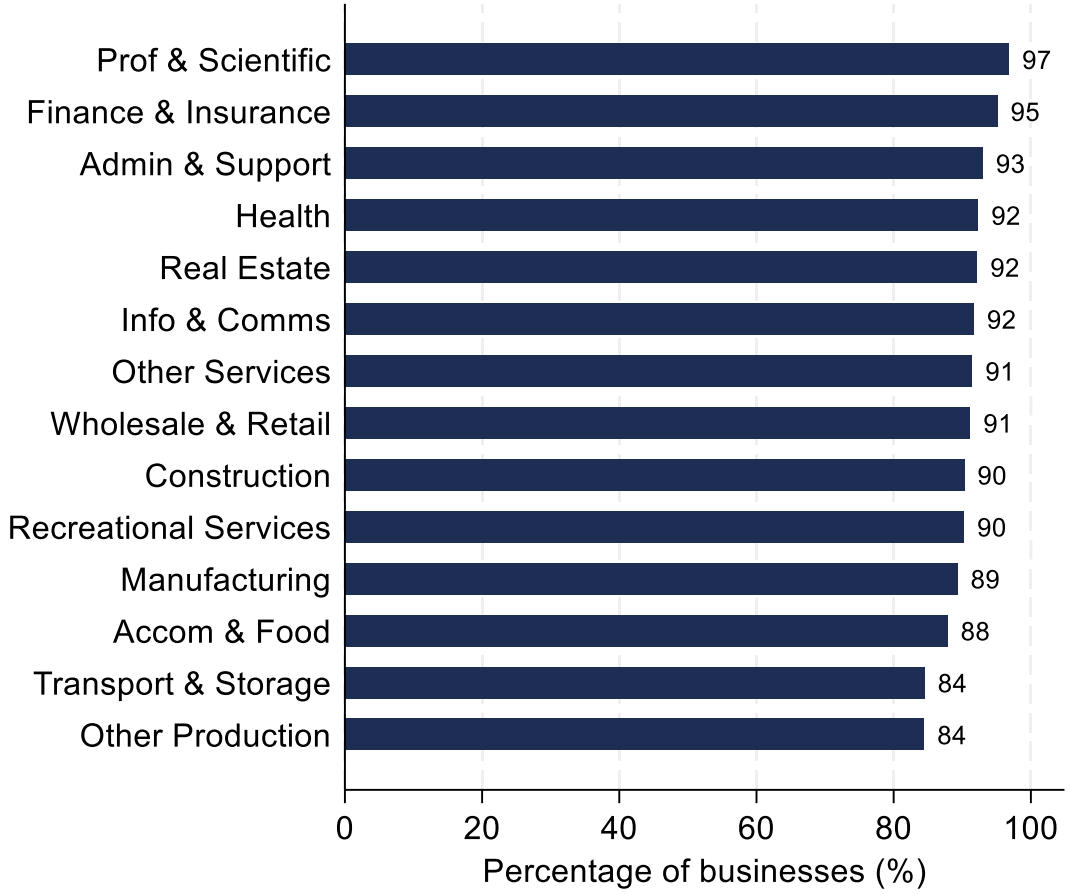

***Notes**: This figure shows binned scatter plots. The vertical axis is the percentage of businesses currently using any AI technology. The data are from the US Survey of Business Uncertainty, collected in November 2025 and June 2026. Labor productivity is defined as sales revenue per employee, and deflated using 2016 gross output deflators.*

SBU Survey of Business Uncertainty

On average, how frequently do you **personally use** AI technologies in a typical working week?

- *Note: Among other things, AI technologies could include text generation using generative AI (e.g. ChatGPT, Claude, or Gemini), data or image processing using machine learning, and visual content creation.*

- ◯ Not at all
- ◯ Up to 1 hour a week
- ◯ 1 to 5 hours a week
- ◯ More than 5 hours a week

SBU Survey of Business Uncertainty

Which of the following artificial intelligence (AI) technologies, if any, does your firm **currently use**?

And which do you expect your firm to use of over the **next three years**?

- *Select all that apply*
- *If you are currently using an AI technology and expect to keep using it, please click both the "Currently using" and "Expect to use in the next 3 years" boxes*

	Currently using	Expect to use in the next 3 years
Generative AI like ChatGPT, Claude, or Gemini	☐	☐
Robotic and autonomous vehicles	☐	☐
Data processing using machine learning	☐	☐
Visual content creation	☐	☐
Image processing using machine learning	☐	☐
Other AI technology	☐	☐
We are not using/do not expect to use any AI technologies	☐	☐

Figure B1 Screenshots of AI survey questions in SBU (continued)

How has the adoption of A.I. technologies affected the volume of SALES PER EMPLOYEE of your business over the **past three years**?

And how do you expect this to affect your volume of SALES PER EMPLOYEE over the **next three years**?

	Past 3 years	Next 3 years
A large negative influence, subtracting 5% or more	○	○
A minor negative influence, subtracting less than 5%	○	○
No material impact	○	○
A minor positive influence, adding less than 5%	○	○
A large positive influence, adding 5% or more	○	○

How has the adoption of A.I. technologies affected the NUMBER OF EMPLOYEES of your business over the **past three years**?

And how do you expect this to affect your NUMBER OF EMPLOYEES over the **next three years**?

	Past 3 years	Next 3 years
A large negative influence, subtracting 5% or more	○	○
A minor negative influence, subtracting less than 5%	○	○
No material impact	○	○
A minor positive influence, adding less than 5%	○	○
A large positive influence, adding 5% or more	○	○

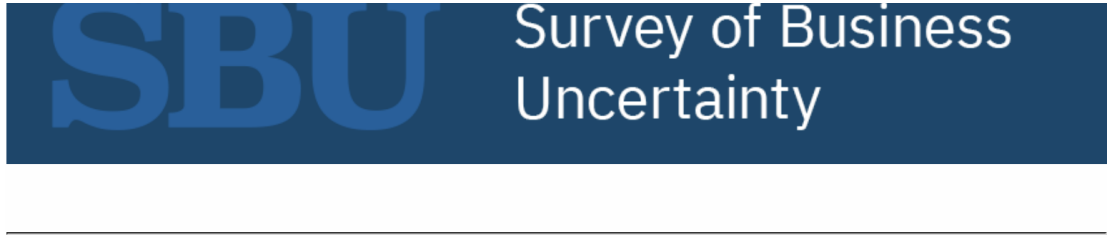

Figure B1 Screenshots of AI survey questions in SBU (continued)

Thinking back to last year -- calendar year 2025 -- how much did your firm spend on A.I. adoption and A.I. related technologies?

- *Include software, subscription services, hardware, worker training, and IT staff support*

About $

Now, think about this year.

For calendar year 2026, how much will your firm spend on A.I. adoption and A.I. related technologies?

- *Include software, subscription services, hardware, worker training, and IT staff support*

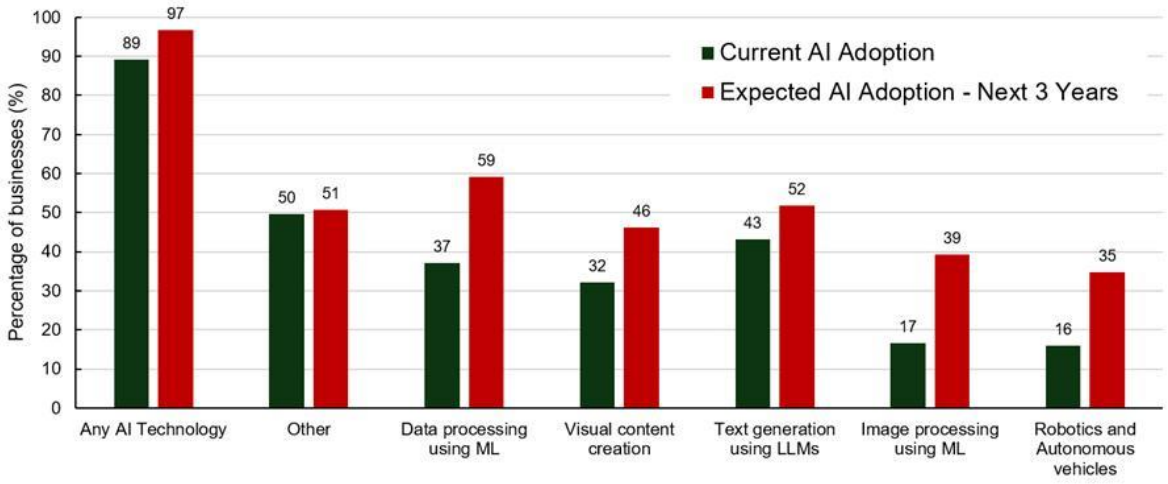

About $

Appendix C. Evidence from the Bank of Korea Firm Survey

The Bank of Korea administered the project's AI survey module online between 15 and 26 June 2026. Given the specific focus of this survey on firms' use of AI, its results are presented separately from the broader cross-country estimates. The survey covered 749 firms with 50 or more employees and was designed to provide broad coverage across major industries and firm-size groups. All five questions were translated into Korean while preserving the structure, economic concepts, numerical thresholds and response categories of the common international questionnaire. The results reported below are weighted by industry using employment shares from the 2024 Korean Census on Establishments.

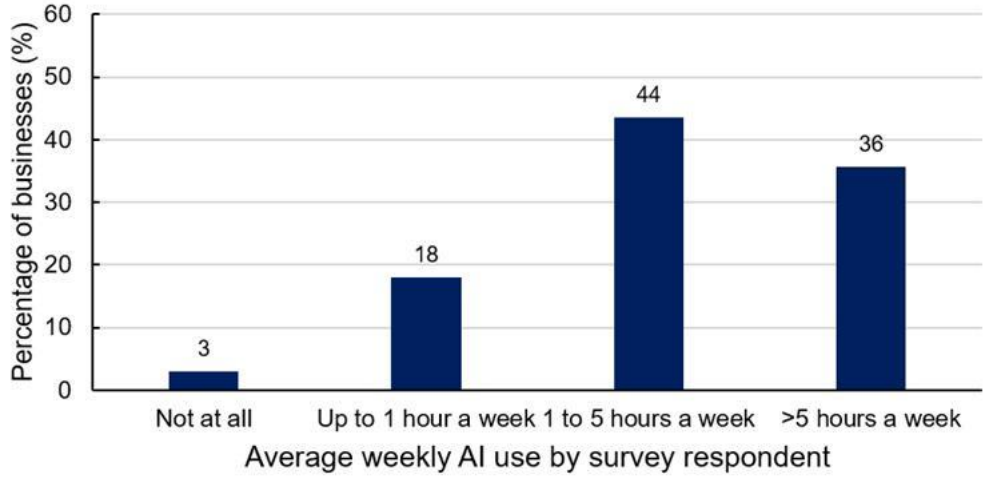

AI adoption among Korean firms was widespread (Figure C.1). An estimated 89% of firms currently used at least one of the AI technologies listed in the survey, while 97% expected to use at least one over the next three years. Current use was most commonly reported for text generation using large language models, at 43%, followed by data processing using machine learning at 37% and visual content creation at 32%. Expected use was higher across nearly all categories, including data processing using machine learning, which 59% of firms expected to use within three years.

Figure C.1 Current and expected use of AI technologies

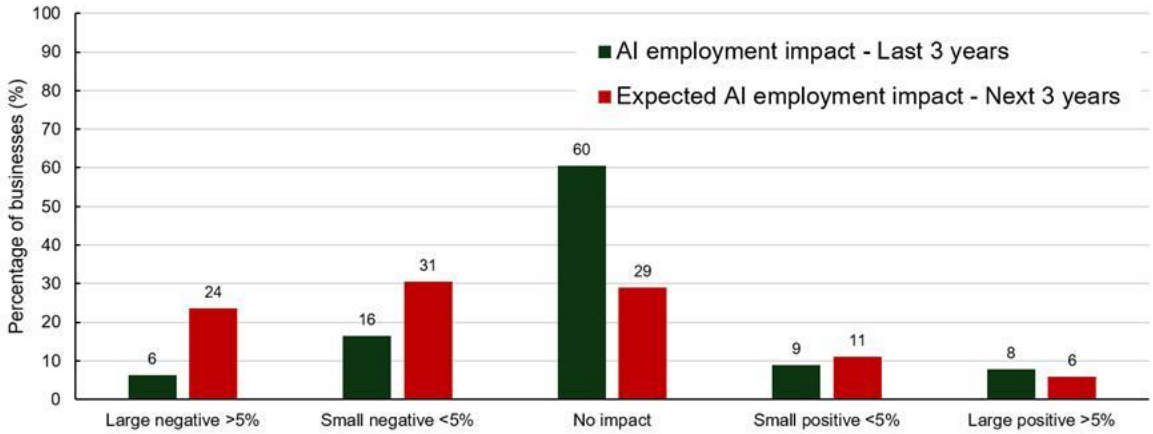

Survey respondents also reported substantially more intensive personal use of AI than respondents in the seven-country sample analyzed in the main text (Figure C.2). Only 3% of Korean respondents reported no use of AI during a typical working week, while 44% used it for between one and five hours and 36% for more than five hours. Applying the same numerical values to the response categories as elsewhere in the paper gives average use of approximately 4.1 hours per week. By comparison, average use in the main seven-country sample was 2.1 hours, with country-level estimates ranging from 1.7 to 2.5 hours.

Figure C.2 Average weekly AI use by survey respondent

Korean firms reported little net effect of AI on employment over the past three years, but considerably more dispersion than in the main sample (Figure C.3). Approximately 60% reported no realized employment effect, compared with more than 80% across the countries in the main analysis. The remaining Korean responses were distributed on both sides of zero: 23% reported a negative effect and 17% a positive effect. Consequently, the implied average employment impact was close to zero, at approximately −0.1%. Looking ahead, however, 54% of firms expected AI to reduce employment over the next three years, including 24% expecting a reduction of more than 5%. The implied average expected employment effect was −1.8%.

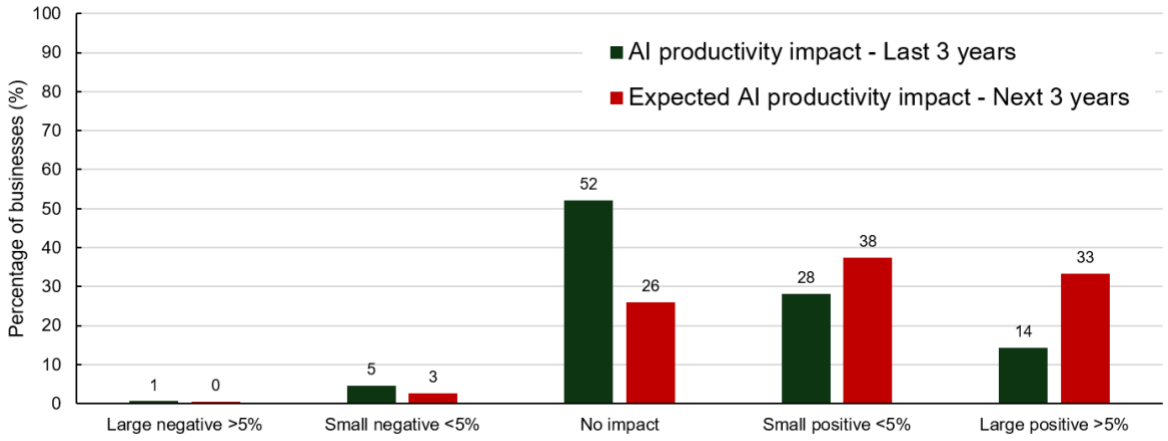

Figure C.3 Realized and expected AI employment impacts

Reported productivity effects were also substantially larger than those in the main sample (Figure C.4). Around 43% of Korean firms reported that AI had already increased sales per employee over the past three years, producing an implied average realized productivity gain of 1.6%. Looking ahead, 71% expected a positive productivity effect, with one-third expecting an increase of more than 5%. The implied average expected productivity gain over the next three years was 3.3%. These estimates compare with average realized and expected productivity effects of approximately 0.4%

and 1.7%, respectively, in the main seven-country dataset.

Figure C.4 Realized and expected AI productivity impacts

The Korean results therefore point in the same qualitative direction as the main findings: AI use is already extensive, realized employment effects are small on average, and firms anticipate larger productivity and employment effects in the future. Quantitatively, however, Korean firms report markedly higher personal AI use and larger expected effects. These differences remain similar under alternative weighting schemes, including employment weighting and a common 12-sector industry weighting. One potentially important distinction is that, whereas the data in the main analysis were collected through ongoing economy-wide business surveys covering a broad range of topics, the Bank of Korea data came from a survey targeted specifically at firms' use of AI. This difference in survey context may have attracted firms or respondents with greater interest in or exposure to AI, or increased the salience of AI when answering the questions, contributing to the larger reported effects. We therefore present the Korean evidence separately rather than pooling it with the seven-country estimates. In future work, we plan to investigate the Korean results further, including by comparing firms' survey responses with other measures of firm performance, such as realized employment and productivity growth.
